BARKING of Dogs, to prevent, 358.
BARNITZ, Cha's A., on his breed of hogs, 201.
BARTON, Rob't R., his address before the Rockbridge Agricultural Society, 282.
BARTRAM GARDENS, near Philadelphia, 208.
BARYTES, as manure, 259.
BASIL, species and culture of, 261.
BATH, a cheap and convenient one, 71.
BAYBERRY, or myrtle wax, its culture, 325.
BEANS, African, sent by Com. Porter to Mr. Skinner, 89. As diet, 358.
BEDDING, of horses in stables, 354.
BEEES, on the housing plan, 23. Large hive of, 30. Sagacity of, 39. Culture of, 70. Preserving in winter, 113. In garrets, 182. Transporting, 199. Profit of, 255. A parasite, 302. Stingless, sent by Mr. Perine, 329. In the garret, 358. Increase of, ib.
BEE HOUSE, new one, 278.
BEE MOTIL, remarks on, 39. Remedy against, 81. 121.
BEEF, fattening, 39. The best machine to turn hay, &c. to cash, 103.
 — **CAKES**, how to make, 415.
BEETS, large one, 257. To preserve, 294. Large one, 297.
BIGELOW, Rev. Jonathan, his address before the Plymouth Agricultural Society, 50.
BIG HEAD in horses, 334.
BIRCH TREES, sap of, makes a fine drink, 39.
BIRDS, bad policy of destroying, 30. How to frighten, 49. Game bird, described by Com. Porter, 59. A rare one, 145.
BLACK TONGUE, in horses, prevention and cure, 353.
BLACK VEILS, how to wash, 9.
BLAND'S grape, 373.
BLANKETS, to preserve from moths, &c., 401.
BLATTERMANN, G., his translation of a chapter of an Arabic work on Agriculture, 402.
BLOOD, soot the best application to stop it, 191.
BLOOMING, of the fringe tree, &c., 121.
BOILING, in cookery, 343.

BON CHRETIEN PEAR, notice of, 253.
BONE MANURE, for corn, 163. For turnips, 305.
BONES, in a man, 271.
BORAGE, use and culture of, 261.
BORER, of apple and quince trees, 277.
BOTANY, Eaton's Manual of, notice of, 5. Of N. Carolina, 198.
BOTS, remedy for, 294.
BRADLY, Dan, on the culture of silk, 236.
BRAN, nutritive matter contained in, 71.
BREAD, method of making, 145. Pone, how to make, 281. Its qualities as diet, 358. Corn, how to make, 409.
BRIGHTON ATHENÆUM, notice and fall of, 262.
BROKEN WIND, in horses, how to cure, 55.
BRONN, Dr., his paper on the influence of seeds on the crop, 275.
BROOM CORN, description and culture, 371.
BUCKWHEAT, as a green crop for manure, 355.
BUEL, Jesse, on manures, 26. On culture of corn, 42.
BUGS, to prevent their destroying vines, 143.
BULBS, forcing to flower in winter, 103.
BUDS, fruit, injured by frost, 401.
BUFFALO BERRY, *Shepherdia argentea*, 208, 266.
BULL, extraordinary one, 71. Chase, in Philadelphia, 355.
BUNCOMBE, Co. N. C., its climate, &c., 279.
BURDOCK, good for King's evil, 191. For hogs, 207.
BURNING CLAY, utility of, 285.
BURTON, Gov., certifies to S. Weller's practice as a vine dresser, 401.
BUSHES, how to get rid of, 305.
BUTTER, how to restore to its original sweetness, 25. Requisites and temperature to make, 95. Making curing, &c., 182. Superiority of Dutch, 263. In New York, 279. To make fresh, 287. Preserving, 359. Winter, 382.
BYEFIELD HOGS, notice of, 231.

C.

CABBAGES, preserving, 287. As diet, 359. Turnip rooted, 377. McEwan's early, 414.
CAKES, beef, how to make, 415.
CALCAREOUS MANURES, essay on, by Edmund Ruffin, 154.
CALF, mammoth one, 241.
CALLA ÆTHIOPICA, culture of, 326.
CALVES, on raising by hand, 23. Diseases in, ib. Sucking, management of, 351. Large ones, 375.
CAMELLIAS, best mold for, 125.
CANONILE, history, use and culture of, 261.
CANAL, in India, for irrigating land, 409.
CANAL NAVIGATION, improvement of, 345. Erie, 345.
CANALS, between Rochester and Olean, 249.
CANEY, S. presents a pair of Ferrets, 249.
CANDLES, improvement in, 38.
CANDLE SNUFF, good for razor strops, 249.
CANKER, in fruit trees, 318.
CANKER WORM, remedy for, 342.
CARAWAY, use and culture of, 261.
CARBON, an elementary substance, 359.
CARROTS, to preserve, 294. Large crop of, 310. Fine ones by Capt. Matthews, 321. As diet, 358.
CARTER, Hill, on the four shift system, 186. On the embankment, &c. of Shirley Swamp, 137.

CASHMERE, or Angora shawl goat, 263.
 CASTOR BEANS, manure from, 195.
 CASTOR OIL, for lamps, discovery of Isaac Smith, 241. Method of cultivating the bean wanted, 313.
 CATALPA, for posts, 135, 193, 225.
 CATAWBA, grape, by E. F. Noel, 372.
 CATERPILLARS, abundance of, 57. To prevent, 89. To destroy, 159. To prevent, 269.
 CATS, Angora, electric property of, 49.
 CATTLE, of Chester county, Pa. report of a committee on a lot of, 22. Different breeds of, considered, 28. Choked to relieve, 47. Disease in, 51. Salt for, 94. Disease among, 199, 191. Milk sickness, 191. Fine ones, 199. Disease among, 207. Distemper among, 239. What breed is best adapted to the south, 219. Fattening, 254. Devon and Shorthorn, 257. Marks of good ones, 309. Durhams, 319, 323. Fattening, 321. Ohio company for importing, 361. Typhus among, 357. Origin and history of the different breeds of, 412.
 CATTLE SHOWS, influence of, 62.
 CAULIFLOWERS, how to cut, 269.
 CAURATZES, for irrigating land in India, 409.
 CELERY, to preserve, 294. As diet, 359.
 CEMENT, fire and water proof, 17, 103.
 CHANGES that take place in imported animals, 355.
 CHARCOAL, preserves timber, 377.
 CHEESE, colored, 318. Remarks on making, 334.
 CHERRIES, the trees indicate a second crop, 262.
 CHERVIL, use and culture of, 261.
 CHESS OR CHEAT, as it is produced only from its own seed, it may be destroyed, by D. T. 28. Experiment on, 172.
 CHESTNUT, the Spanish, its culture, 86. Timber, 108.
 CHICK IN THE EGG, its progress, 105.
 CHINESE MULBERRY, its value for silkworms, 254, 266, 319.
 CHOICE of a pursuit, 175.
 CHRONOLOGY, dates of the introduction of various productions, 246.
 CHURNING, on horseback, by the Buenos Ayreans, 87.
 CIDER, how to clarify, 58. On making, 101, 238. To purify musty, 333.
 CIDER MILL, grater, notice of, 204.
 CLARY, use and culture of, 261.
 CLAY, utility of burning, 285.
 CLOVER, in Virginia, 122, 149, 194. And Wheat, 212. Ploughing in for wheat and corn, 233, 249. Improvements by, 298. As a green crop, 355. Sown among corn, 409.
 ——— flesh colored, by John Lowell, 379.
 ——— AND TIMOTHY, after wheat, 412.
 CLOVERSEED, sown early, 175.
 COAL, stone, as manure, 259. In Virginia, 369.
 COBBETT'S COTTAGE ECONOMY, notice of, 65.
 COCKROACHES, how to destroy, and how to get rid of, 41.
 COCOONS, a market for, in Baltimore, 97. Value of, their qualities, &c. 129, 392. Exhibited at New York, 319.
 COFFEE, to burn properly, 388.
 COLMAN, Mr. extract from his address, 415.
 COLUMBIA, climate and productions of, 159.
 COLTS, breaking them, 310. Management of, 311.
 COLUMBUS, introduces various articles, 246.
 COMBS, tortoise shell and horn, 246.
 COMPASS PLANT, seed of, received, 1, 73.
 COMPOSITION, for trees, 317.
 COMPOSTS, for improving land, 251.
 CONSTANTIA, grape, 453.
 COOKERY, general operations of, 342.
 COOKING, food for horses, 163. Animal food, loss in, 335.
 CORIANDER, use and culture of, 262.
 CORN, account of a crop of, 1. Culture of, 35. The varieties of, ib. Culture of, by J. Buel, 42. Culture of, with peas, 81. Culture of, 84. Cutting early in the fall, 108. Experiment with, 123. Preparation for, 148. Preparing seed, 163. Bone manure for, 163. Smith's early, notice of, 137. By J. Love, 177. Early, 209. Early gathering of, 228. Great crops of, 243, 269. In double drills, 266. Its discovery, 269. Salt on, 273. Dwarf, its advantages, 276. Sweepstakes proposed, 389. Culture of, 396. A fine crop of, 377. Best kind for meal, 409.
 ——— BREAD, how to make, 409.

CORN CROP, culture of a, 386.
 CORN SHUCKS for mattresses, 273, 345.
 CORN STALKS, saving labor in cutting, 276.
 COTTON, large stalk of, 14. Preparation for a crop, 211. Culture of, 252. Fine crop of, 276. Crop of Mississippi, 278. Crop of this year, 297. Salt for improving its staple, 337. Hoax exposed, 333. Why is it warm, 311. Rot in, 379.
 COTTON SEED OIL, mill for extracting, 89. Manufacture of, 193. By T. Follet and J. Smith, 222. Its value, 263. Manufacture of, 271. Machine for, 299.
 COUPER, J. H. on rotation of crops, 2, 12.
 COWS, milk, excellence of manzold wurtzel for, 25. Intended to fatten, 39. Best breed, 153. Milked by hogs, 257. Marks of good ones, &c. 278. Milk, character of, 302. Management of, in Paris, 341. Feeding, &c. 351. Plants eaten by, 343. Milk, best mode of keeping in winter, 357. Require salt, 363. One that sucks herself, 383. Native American, the best, 357. Milking of, 389.
 COW, and Wife, wanted, 241.
 CRAB APPLE, rock of Dumbarton, 185.
 CRABS, their natural history, 247.
 CRANBERRY, high bush, notice of, 86.
 CREAM, new process of obtaining, 143. Heating in making butter, 382.
 CREDIT, of articles from newspapers, 273.
 CREEKS AND RIVERS, on clearing the margins, 79.
 CRINUM, *amabile*, notice of a splendid one, 81.
 CROP, of corn, 4.
 CROPS, rotation of, by J. H. Couper, 2, 12. Course of, 58. Not so bad, 191. In Mississippi, 289.
 CROUP, remedy for, 219.
 CROWS, how to catch, 255.
 CRYING CHILDREN, how to relieve of collapse of the lungs, 49.
 CURCULIO, notice of, 53, 150, 269, 277.
 CURD AND WHEY, cures dyspepsia, 265.
 CURRANT BUSHES, ornamental, 398.
 CURRANT LEAVES, make good tea, 377.
 CURRANTS, culture of, 333.
 CHRYSANTHEMUM, indicum, method of cultivating, 164.
 CYAMUS, lutens, described, 37.
 CYPRESS TREE, the oriental, seeds of, received from Com. Porter by J. S. Skinner, 65.
 CYPRESS, European, remarks on, 256.

D.

DAHLIAS, large number planted by the Editor, 73. To preserve, 241. In England 310.
 DAY BOOK, farmers should keep one, 353.
 DARLINGTON, Dr. Wm., on the use of lime in agriculture, 34.
 DEBT, keep out of, 367.
 DEPOSITS, removal of, a dun, 321.
 DERBY, E. H. his crop of turnips, 412.
 DEVON, (north) cattle, essay on, 315, 323. Their qualities, 348. Good milk, 369. Compared with Durhams, 359.
 DEVON BEEF, slaughtered, 305.
 DICKENET, H. F., proposes to publish the Magazine of Gardening and Botany, 321.
 DIET, of laborers in Scotland, 343.
 DIGEST, a new idea, 313.
 DIONEA, *Muscipula*, plants of, received, 121.
 DISEASES, in horses and cattle, 207, 230. General cause of, 279.
 DISTEMPER, among cattle, 230.
 DICHLING, economical method of, 126, 330.
 DOCK, narrow leaved, fertilizes land, 221.
 DOGS, to prevent their barking, 388.
 DOMESTIC ANIMALS, breaking steers and colts, 340. Management of colts, 341. Nourishing milk cows in Paris, in Improved stock, 348. Treatment of, 351. Different breeds of sheep, 356. Sheep, cattle, &c. 357. Breeds of, 361. Breeds adapted to the soil, 371. Wintering sheep, 372. Live stock at the Albany fair, 380. Breeding horses, ib. What breed is best for milk cows, 378. Selection and management of sheep, 397. Durham Shorthorns, 404. Treatment of early lambs, ib. Wintering sheep, care of lambs, &c., 403. Origin and history of the different breeds of cattle, 412.
 DRAINING, an important operation in husbandry, 75. Essay on, 330.

DRESS, economy in, by Cobbett, 399.
 DRILL, recommended by Mr. Garnett, 268.
 DROUGHT, severe in May, 65, 73, 209, 241. Stirring the earth to, 268.
 DUCHESS of Angouleme pear, notice of, 253.
 DUCKS, successful method of raising, 6.
 DUNHILL, management of, 162, 195.
 DURHAM SHORTHORNS, their qualities, 348. Compared with Devons, 350, 404.
 DWARF CORN, its advantages, 276.
 DYSPEPSIA, cure for, 265. From mince pie, 313.

E.

EASTMAN, J. S., on Fox and Borland's threshing machine, 393.
 EARTHS, proper combination of, 259. Analysis of, 314, 322.
 ——— the, a huge animal, 399.
 EATON'S Manual of Botany, notice of, 5.
 ECONOMY, among farmers, 183.
 EDITORS, requested to publish advertisement, 241.
 EDUCATION, of farmers, by Philip Lindsley, 103, 238, 241, 255, 270, 271, 273. Public, 303. Universal, 321, 327. Extract from an address on, 335. Universal, 343, 369. Remarks, 399.
 EGGS, preserving, 318.
 ELEMENTARY SUBSTANCES, of vegetables and animals, 359.
 EMIGRATION, at Buffalo, 111.
 ESCULENT ROOTS, on their culture, 403.
 EWE, a prolific one, 143. An old one, 297.
 EXECUTIONS, reflections on, 329.
 EXPENSE, of a system of farming, 378.

F.

FALL, the time to transplant, 262.
 FALL SOWING, of vegetables, 377.
 FALLOW, its various meanings, 227.
 FALLOWS, summer, their use recommended, 3. Manuring of, for wheat, 308.
 FARMER, how to make, 233. Profession of, 303. The, a poem, 399.
 FARMERS, education of, 103. As they were and are, 183. Should communicate their experiments, &c., 265.
 FARMER'S REGISTER, notice of its commencement, 121.
 FARMING, a letter on southern, 41. System of, by J. H. C., 130. In York county, Va., 226. And grazing in Virginia, 316.
 FARMS, on renting, 9. By Sir John Sinclair, 10.
 FATTENING Cattle, best method of, 251. Hogs, ib. 286. Hogs, on apple pie, 327.
 FEASTS' Gardens, notice of, 209.
 FEATHERS, for use should be plucked soon, 30.
 FECUNDATION, of seeds, 281.
 FEELNBURG INSTITUTION, letter from Mr. Morris on, 105.
 FENCES, bad economy of bad ones, 7. Live, 43. Different kinds of, 47. Should be repaired, 63. By Gen. W. H. Harrison, 135.
 FENCE POSTS, to preserve, 415.
 FENNEL, use and culture of, 262.
 FERMENTATION, of manures, experiments on, 202. Of food for cattle, 286.
 FERNS, duration of the germinating principle of their seeds, 219.
 FERRETS, a pair presented by S. Canby, Esq., 249.
 FIBROUS PLANTS, on their culture, by Dr. Perine, 38.
 FIGS, in New Holland, 273.
 FIRE, in the woods of New York, 65.
 FISTULA, cure for, 367.
 FLAX, to succeed potatoes, 58. Culture of, 106. New Zealand, 387.
 FLIES, to prevent their annoyance, 289.
 FLINT, Waldo, his address before the Worcester Agricultural Society, 66.
 FLORIDA, suitable for tropical plants, 191. Looked to by the West Indians, 269. Cotton in, 276.
 FLOUR, of potatoes, in France, 73.
 FLOWERS, English partiality for, 71. New and valuable ones, 109. Vernal, 108. Suppressing those of the potato, 285. Odorous matter inflammable, 302.
 FLYING SQUIRREL, its natural history, 158.
 FODDER, on drying, 59.
 FOLLET, F. and J. Smith, on cotton seed oil, 222.

FOOD, of seamen, remarks on, 63. Relative nutritive properties for cattle, &c., 95. For fattening cattle, &c., 286.
FOREST LOTS, should be saved, 382.
FORKS, steel, to clean, 407.
FOUR SHIFT, in rotation of crops, 185, 298.
FOXGLOVE, injurious to goslings, 191.
FRESHETS, loss of grain by, 145.
FROGS, indicate the weather, 414.
FROMONT, Villa of, notice of, 246.
FRUIT, new, the berberis parviflora, account of, 29. Of the means of prolonging varieties of, 100. Finest kinds should be chosen, 150. To obtain new varieties, 221. Finest in Virginia, 253. Is it affected by the farina of other kinds, 265, 273, 281. Injury to by frost, 401.
FRUIT TREES, to check the growth of, and promote fruitfulness, 21. Culture of, 36. Wash for, 73. To free them from caterpillars, 89. In the collection of Van Mons, 229. Watering, 318. Canker in, ib. Low temperatures injurious, 401.
FUEL, economy in, 399.
FURNITURE, economy in, 399.

G.

GAMA GRASS, remarks on, by H. B. C. 157. By W. B. Mears, 171. By N. Herbemont, 177. Its botanical character, 197. Remarks on, 222, 241, 283. By R. B. Mason, 289. In North Carolina, 293. By W. B. Mears, 303.
GARBER, J. B. sends specimens of seedling grapes, 217.
GARDENING, in the vicinity of London, 81. Its importance, 94.
GARDENS, robbing, 145. Kitchen, formation of, 380.
GARDEN SEEDS, duration of their vitality, 157.
GARDEN VEGETABLES, fall sowing, 377.
GARLIC, to rid wheat fields of, 297.
GERMINATION of seeds, 161.
GLANDERS, in horses, treatise on, 109.
GLAZED CALICO, sewing, 65.
GOATS, Angora, letter from Com. Porter to J. S. Skinner, on importing, 49. Further notice of, 263.
GOOCH, C. W. his prize essay, 138.
GOOSEBERRIES, culture of, 333.
GRAFT and Stock, influence of, 29.
GRAFTING, directions for performing it, 36, 86. — Grapevines, by S. Weller, 406.
GRAFTED TREES, seedlings from, 318.
GRAIN, large quantity raised, 265. Portion wasted, 285.
GRAPES, culture of, by Dr. J. C. S. Monk, 4. The Herbemont Madeira, 21. Rot in, by N. Herbemont, 142. The Norton seedling, 209. Seedling, by J. B. Garber, 217. Isabella, and Schuyllkill muscadelle, 233. In Ohio, 326. Remarks on, 312. Pine, 345. Native and foreign, 372. Propagation, 374. American, 414.
GRAPEVINES, the great one, of Mr. Willis, 89, 113, 129, 41. By S. Weller, 266. Large ones, 269. Autumn management of, 294. Culture, 301. Culture of, 315. Foreign, 406. Best varieties, ib.
GRASSES, cultivation of, in the south, 85. Culture of, in Virginia, 411.
GRASS LANDS, should be top dressed, 69.
GRASS SEEDS, time and manner of sowing, 403. Sown under corn, 429. Should be sown after wheat, 412.
GRATER CIDER MILL, notice of, 201.
GRAZING, in Virginia, 376.
GREASE SPOTS, removed by pearl ash water, 355.
GREEN CROPS, turning in, for manure, 355.
GREEN STEM, apple, specimen of, 233.
GREYHOUNDS, presented by Gen. Jackson, 233.
GRUBBING PLOUGH, inquiry for, 305, 313.
GRUBS, and Bots, remedy for, 294.
GUINEA GRASS, introduction of, in Jamaica, 246.
GUELIBRISCHIM, seeds of, sent to the Massachusetts Horticultural Society by Com. Porter, 101.
GYPSEOUS EARTH, essay on, by E. Ruffin, 218.
GYPSEM, from Smyth county, Va. 236. Of New York, 258.

H.

HAMS, receipt to cure, 71.
HARDEN, Dr. R. R. on painting houses, 61.
HARVEST, generally plentiful, 252.

HAWKS, to frighten birds, 49.
HAY, on the management of, 170. Should be cut for horses, 389.
HEAT, essential to vegetation, 93. Without fuel, 295.
HEDGES, prickly ash for, 17. Different plants for, 43. Those near Philadelphia, 53. Remarks on, 174.
HEMLOCK, water, injurious to cattle, 191.
HEMP, culture of, 59. By L. E. Lathrop, 378. Machine for spinning, 239.
HENS, how to make them lay in winter, 37. Confined, 343.
HERBEMONT, N. on the vine, 142. On gama grass, 177. Notice of, by S. Weller, 405.
HERBS, natural history and culture of, 261, 300.
HESSIAN FLY, to avoid, 213. Simple method of destroying, 243, 244, 356.
HINTS, to housewives, 87. Practical, 93.
HITCHCOCK, L. L. his introductory address, 233.
HOG COMMITTEE, Porcus' letter to, 327.
HOGS, on penning them, 14. Scalding, 30. Sows and pigs, 47. Barnitz breed of, by Chas. A. Barnitz, 201. Burdock for, 207. Byfield, 231. Fattening, 254. Milking a cow, 255. Large one, 269. Fattening on apple pie, 327. Changes that take place when imported, 365. Importance of selecting best breeds, ib. Of Mexico, 365. Management of, at the south, ib.
HOLBROOK, E. account of his crops, 297.
HONEY, poison from new, 193.
HONEY BEE, its cultivation upon the housing plan, 23. Large hive of wild ones in a rock, 30. Sagacity of, 59. Culture of, 70. Preserving in winter, 113. In garrets, 182. Transporting, 193. Profits, &c. 255. Its parasite, 302.
HOPS, advance in price, and their culture, 249, 265. Culture of, 267, 300. American preferred in Holland, 399.
HORIZONTAL, and hillside ploughing, origin of, 57, 82.
HORSES, broken wind in, 55. In farming, 58. Glanders in, 109. Turkish, 111. Feeding, 126. Niek-ing, reprobated, 145. Cooking food for, 165. Disease among, 207. Injured by treading wheat, 221. Drink for, 235. Fed on steeped barley, 278. Shoeing in Flanders, 283. Oil keeps off flies, 289. Yellow water in, 303. Big head in, 334. Cutting their tails off, 345. Curing vicious ones, 351. Sore tongue in, 359. Changes when imported, 365. Fistula in, 367. Expense of raising, 370. On breeding, 383.
HORSE RADISH, to preserve, 294, 318.
HORSE RAKE, description of, 184, 199.
HORTICULTURE, lecture on, by L. F. Allen, 132.
HORTICULTURAL CHEMISTRY, scraps of, 317. — MAGAZINE, notice of a proposed work by this title, by Mr. Diekhut, 89. — SOCIETY, of Maryland, plan of exhibition, 25. Plants exhibited, 33. Do. 41. Exhibition notice, 57. Programme of, 97. Proceedings of the Massachusetts, 101. Exhibition of the Maryland, 105. Report of, 113. Address before, 116. Offer premiums, 137. London, 157. Charleston, 173. Address before the Charleston, 189. Of Charleston, address before, 189, 213. Of London, 193. Of Pennsylvania, 201. Of Newburg, 244. Of Albany, 245. Pennsylvania, 245. Of New York, 252. Of Maryland, proceedings of, 313. Hammocks, &c. received from Dr. Perine, 377. Grapes, &c. 385.

HOUSES, on building, 57.
HOUS SERVANTS, Directory, notice of, 383.
HYACINTHS, forcing in winter, 108.
HYDROGEN, an elementary substance, 359.
HYSSOP, use and culture, 300.

I.

IGNORANCE, evil of, 369.
IMPLEMENTS, improvements in, 58.
IMPROVEMENT, of poor land, the best mode required, 9. In Maryland, 205. Effected by industry and temperance, 329, 333.
IMPROVED DURHAM SHORTHORNS, remarks on, 404.
INDEPENDENCE, what is it? where is it? 129.
INDIAN CAKES, or pone, 287.
INDIAN CORN, its discovery, 269.
INDIA, British, plants of, 68. Irrigation in, 409.
INFLUENCE, of the origin of seeds on the crop, 275.
INK SPOTS, to extract, 343.

INSECTS, in hot beds, to destroy, 135. On peach trees, 269, 277, 297.
INTERNAL IMPROVEMENT, judicious, by C. W. Gooch, 140. Canal between Rochester and Olean, 219, 263, 281.
IRON, cast, will crack if cold water be thrown on it while hot, 401.
IRRIGATION, advantages of, 59. In India, 409.
ISABELLA grape, by E. F. Noel, 373.
IVY, preventive of its poison, 175.

J.

JACK, a fine one sold to Mr. Clay, 273.
JACKSON, Gen. presents greyhounds, 233.
JOHNSTON, L. his machine for bulling cotton seed, 299.

K.

KENNEDY, John P., his address before the Horticultural Society, 116.
KING OF OIL, sovereign remedy for wounds in cattle and horses, 7.
KING'S EVIL, remedy for, 191.
KITCHEN GARDENS, formation of, 380.
KNIVES, to clean, 407.
KOHL RHABB, turnip rooted cabbage, 377.

L.

LABOR, rural, beneficial to professional men, 65. Great feat at, 313. Remarks on manual, 370.
LAFAYETTE COLLEGE, at Easton, Pa., 255, 270.
LAMBS, early, treatment of, 404.
LAMP WICKS, to prepare, 246.
LAND, improvement of worn out, 122. In Maryland, 205. Value of in Pennsylvania, 273. Treatment of, 409. Value of, in Virginia, 411.
LAND-DITCHING, economy of, 126.
LAPHAM, S., on the culture of silk, 353.
LAPHAM, J. A., suggests the publication of the American Farmer's Library, 491.
LARD, hog's, a remedy for cattle, &c., 319.
LAVENDER, use and culture, 300.
LAZY, how to punish the, 247.
LEAVES, sleep of, 70. Preserved as fodder, 123. Make good litter, 343.
LEMONS AND ORANGES, to preserve their peel, 401.
LEWIS, Fielding, memoranda of his system of cultivation, 146.
LEVEL ROADS, not always best for horses, 7.
LIBRARY, American Farmer's, a work with this title suggested by J. A. Lapham, 491.
LIBRARY OF ENTERTAINING KNOWLEDGE, notice of, 55.
LIFE, duration of, in various animals, 414.
LILY, of the Scriptures, is the *lilium candidum*, 29. Of the Nile, culture of, 326.
LIME, on its use in agriculture by Dr. Darlington, 34. Burning in a common fire, 49. A constituent of bones, &c., 86. As manure, 251. Its properties, 314. Its advantages as manure, 386. Makes apple trees fruitful, 407.
LINDLEY'S GUIDE, to orchardists, notice of, 70.
LINNEAN BOTANIC GARDEN, Prince's, visit to, 125.
LIMES, from Florida, 191.
LITTERING, stable yards, 354.
LIVE FENCES, plants best adapted to, 43, 116, 174.
LIVE STOCK, introductory remarks on, 321.
LOBELIA, inflata, produces slobbering, 191. Gracilis, 198.
LOCUST, yellow, culture of, 5, 73, 217.
LOUISIANA, description of lands, &c., 127.
LOW LANDS, best method of reclaiming, 92.
LUCERNE, culture of, 85, 163.
LUPINS, transplanting, 141.

M.

MACHINE, stocking knitting, notice of McMullen's, 1. For spinning silk, 38. Machine to turn produce to cash, 103. Patent, 217. For spinning hemp, 239. Sawing boards lengthwise, 249. Cotton seed oil, 259.
MADNESS, its reasoning power, 393.
MAGAZINE OF GARDENING AND BOTANY, by H. F. Diekhut, 321.
MAGNESIA, its properties, 314.
MAGNET, Professor Henry's, 265.

MAGNOLIA, macrophylla, in Florida, 121.
 MAIL, irregularity of, 257.
 MAINE, state of, its produce, 291.
 MANGOLD WURZEL, for cattle, its value, 25. Its culture, 53, 242. Great crop of, 251.
 MANURING, in the hill, 412.
 MANURES, remarks on saving and using, 19. For grass land, 20. Essay on, by Jesse Buel, 26. For wheat, 31. Manner of applying, 52. Specific, 122. Putrescent, 148. Summer fermented, 150. Calcareous, 154. Dunghill, 162. Bone, 163. From castor beans, 195. Farm dung, 195. Fermentation of, 202. Application of, 266. Different kinds of, 250, 258. Absorbent properties of various, 317. A paper read before the Eastern Shore Agricultural Board, 354. Manures, 357. Notice of Naboth's communication on, 355. Distributing, 386. Marine, use of, 410.
 MANUFACTURAL PLANTS, should be cultivated, 70.
 MARIGOLD, use and culture, 301.
 MARJORAM, use and culture, 301.
 MARL, rock, found in Prince Edward co. Virginia, 1. In New Jersey, 212. In a new district, 231.
 MARLING, remarks upon, 220, 226.
 MARSH MUD, as manure, 354. With lime, 356. As manure, 410.
 MASON, R. B. on gama grass, 289.
 MATTHEWS, Capt. W. P., presents carrots and parsnips, 321.
 MATTRESSES, of corn sheaves, 273, 345.
 MEADE, R. K., notice of the sale of his stock, 33. On Agricultural Schools, 91. Report of the sale of his stock, 97.
 MEAL, to keep cool, 246. Corn, should not be too fine, 409.
 MEARS, W. B., on gama grass, 393.
 MEASE, Dr. James, on girdling trees, 151.
 MECHANICS, encouragement of, 370.
 MELON, the striped housaince 151. Of Bokaria, 302.
 MELONS AND SQUASHES, experiments with, 41.
 MEMORANDA, valuable, 121. Of a system of cultivation, &c., 146. Of a journey from Newbern to Raleigh, 198.
 MERCHANTS AND MILLERS, on their regulating the prices of wheat, 169.
 METEOROLOGICAL Journal for February, 15.
 MICE and Rats, attracting and destroying, 295.
 MILK, for the bite of a snake, 333. To remove the taste of garlic from, 334. Quality of, 369.
 MILK SICKNESS, in the western country, 191.
 MILKING COWS, instruction in, 389.
 MIND, culture of, 375.
 MINERAL PITCH, in Trinidad, 135.
 MINT, use and culture, 301.
 MOLASSES, should be boiled, 305. For preserving fruit, 311.
 MONKIE, Dr. J. C. S., on the culture of grapes, 4.
 MOON, how to cheat her, 21. Influence of, 161, 166, 262.
 MORRIS, Anthony, letter from, on his Fellenburg School, 105.
 MORUS MULTICAULIS, its value for silk worms, 251, 266, 310, 313. By W. Kenrick, 366.
 MOTHS, to prevent, 377.
 MOTH WEAVER, its propagation and prevention, 290.
 MOUNTAIN RICE, account of, 31.
 MOWING wheat, advantages of, 233.
 MUD, weight of that daily in the Ganges, 49.
 MULBERRY, new Chinese, its value, 254, 266, 310, 313. By W. Kenrick, 366.
 MULES, large number sold, 269.
 MUSTARD, why buy, when you can grow it, 65. Large, 161. A remedy for poison, 287.
 MYRTLEWAX, culture of, 325.

N.

NABOTH, on manures, 356.
 NANKLEN, American, notice of, 113, 225. To color, 325.
 NEEDY, and the needful, 241.
 NEW DISCOVERIES, remarks on, 215.
 NEW YEAR, remarks on the, 357.
 NEW ZEALAND, first wheat in, 276. Flax, 287.
 — SPINACH, notice of, 52.
 NICKING HORSES, reprobated, 145.
 NITROGEN, an elementary substance, 359.
 NORTH CAROLINA, customers served, via. New York, 265.

NORTH DEVON CATTLE, essay on, 315, 323.
 NUTRITION, in different vegetables, 22, 351.

O.

OATS, Chinese skinless, 289. Account of, 367. As diet, 358. Large, or potato, 361. Does the oat crop exhaust the soil, 393. Exhausts the soil, 409. The Hopetown, 114.
 OBSTACLES, to the diffusion of Agricultural Science, 319.
 OFFICES, evils of inordinate ambition for, 51.
 OHIO, agriculture in, 207. Vineyards in, 326.
 OIL, of cotton seed, mill for extracting, 59, 198. Prevents annoyance from flies, 289.
 OILED SILK, its use, 318.
 OLIVE, varieties and remarks on, 236.
 ONIONS, raised at Headfield, 262. To produce large, 342. As diet, 39.
 OPIUM, American, production of, 206.
 ORCHARDS, culture and management of, 36. In miniature, 37. Robbing, 145.
 ORCHARD GRASS, its nutritive properties, 265. Time of sowing, &c. 268. Does not produce slobbering, 278.
 OWE no man, good advice, 367.
 OXEN, loss in fattening, 111. Extraordinary one, 121. Grey oxen of Italy, 161. Their value for hauling, 357. Expense of raising a yoke, 371.
 OXALIS crenata, substitute for the potato, 53, 414.
 OXYGEN, an elementary substance, 359.
 OYSTER SHELLS, burning and applying, 147.
 OYSTER SHELL LIME, as manure, 410.

P.

PAINTING HOUSES, improvement in, by Dr. R. R. Harden, 61.
 PALM TREE, its various qualities and uses, 1.
 PARMENTIER'S GARDEN, sale of, 278.
 PARSLEY, use and culture, 301. As diet, 359.
 PARSNIPS, to preserve, 294. Fine ones, 321. As diet, 359.
 PASTRY, its qualities as diet, 358.
 PASTURES, permanent, their propriety questioned, 93. 107. Good, necessary to good milkers, 153. Great yield, 309.
 PATENT MACHINES, impropriety of noticing all, 217.
 PATRICIAN, pedigree of, 199.
 PEACH STONES, to preserve and plant, 209.
 PEACH TREES, worm in, 253, 269. Cultivation of, 389.
 PEARS, good sized one, 239. Bonchretien, 252. Duchess of Angoulême, 253.
 PEAR TREES, girdling, by Dr. James Mease, 151.
 PEAS, cow culture of, with corn, 83. Marrowfat, in the field, 85. Raising, for swine, 100. Field, 122. Green, price of, in London, 287. As diet, 358.
 PEAT MOSSES, and shell marl, 196.
 PEDIGREES, of Patrician, Saccharissa, and Young Trojan, 199.
 PENNING HOGS, utility of, 14.
 PENETRATION, quick, 375.
 PERINE, Dr. sends stingless bees and Sisal hemp, 329. Sends Sisal hemp, stingless bees, &c. to the Horticultural Society, 377.
 PENNYROYAL, use and culture, 301.
 PEONIES, notice of, 108.
 PEPPERMINT, use and culture, 301.
 PHYSIOLOGY, vegetable, lecture on, 76.
 PICKLES, how to prepare, 233. Red cabbage, 281.
 PIERCE, Joshua, sends specimens of a crab apple, 185.
 PIGEONS, wild, peculiar habits of, 126.
 PIGGERIES, of Mexico, 365.
 PIGS, raising from cuttings, 377.
 PINES, of North Carolina, 358.
 PISMIRE, to guard against, 191.
 PITCH, mineral, in Trinidad, 135.
 PLANTAINS, from Florida, 191.
 PLANTS, in Carolina, 198. And seeds, sent by Dr. Perine to New Orleans, 153.
 PLANTING, forest trees on waste land, 14. To the greatest advantage, 53.
 PLASTER, its action near salt water, 411.
 PLATE, to clean, 415.
 PLOUGH, a new one, 169.
 PLOUGHING, in hot dry weather, 49. Deep and shallow, 52. Horizontal and hill side, 57, 82. Deep, 98. In dry weather, 102. Deep, 130. Fall, 300. Winter, 308. Deep and shallow, 370.

POISON, to prevent from ivy, 175. Remedy for, 287.
 POKE BERRIES, propriety of their use, 281, 305.
 POLISHED VESSELS, best to retain heat, 87.
 PONE BREAD, recipe for, 281, 287.
 PONY, singular sagacity of one, 1.
 POOR LAND, how best improved, 9.
 POPLAR, a large log of, 389.
 POPPIES, transplanting, 141.
 PORTUS, his letter to the Hog committee, 327.
 PORTER, Com. on Angora goats, 49. Electric propriety of Angora cats, ib. Sends seeds of African Beans, and describes a game bird, 89. Letter to the Massachusetts Horticultural Society, with seed of the gaul ibrischim, 101.
 PORTER, J. M. on the LaFayette College at Easton, 255.
 POSOLE, and Sacea of Mexico, how to make, 145.
 POSTS, catalpa tree for, 135, 153. To preserve fence, 415.
 POTASH, its absorbent properties, 102.
 POTATOES, culture of, 52. New species of, 53. Two crops of, ib. Varieties of, 59. New, in March, 84. Introduction of, 85. Raising, in Virginia, 99. Experiments with, 123. Planting Irish, 172. The Mercer, 180. Early, new way to grow, 244. Frosted, 270. To preserve, 279. Suppressing the blossoms, 285. Preserving, 287. To prepare cold, ib. For horses, 311. Culture of, 340. As diet, 358. Substitute for sweet, 369. For live stock, 403. Taylor's forty fold, 414.
 — VINE, long one, 260.
 — SLIPS, to preserve, 293.
 — PASTE, how to make, 53. Flour, 73.
 POULTRY HOUSES, construction, &c. 326.
 PRAISE, like ambergris, 303.
 PREMUMS, offered by the Md. Hort. Soc. 137.
 PRESERVING, garden vegetables, 287.
 PRICES, of wheat, 169, 185.
 PRICKLY ASH, for hedges, 17.
 PRINCE, Wm. & Sons, their new products, 414.
 PRIZE ESSAY, by C. W. Gooch, 105.
 PRODUCTIONS, of the earth, importance of dispersing, 246.
 PROFESSORSHIP, of rural and sylvan economy, 273.
 PRUNING TREES, remarks on, 22.
 PUMPKINS, large ones, 14.
 PUMPKIN BREAD, by T. Bridgeman, 367.
 PYRITES, used as manure, 258.

Q.

QUERIES and answers read before the Board of Agriculture of the Eastern Shore, 205.
 QUINCE TREES, remedy for the worm in, 101.

R.

RADISHES, to grow fine ones, 41. Large ones, 137, 273. As diet, 359.
 RAIL ROADS, in N. Carolina, 247. Atlantic and Mississippi, 385, 390.
 RAIL ROAD JOURNAL, American, notice of, 273.
 RAIN, depth of in May, 105. Depth of fallen, 407.
 RAKE, horse, description of, 183, 199.
 RASPBERRIES, culture of, 323.
 RASPBERRY CORDIAL, how to make, 101.
 RATS, in a cornfield, 47. And mice, attracting and destroying, 295.

AMERICAN FARMER.

RURAL ECONOMY, INTERNAL IMPROVEMENTS, PRICES CURRENT.

"O fortunatos nimium sua si bona norint
Agricolae."

Vol. XV.

BALTIMORE, MARCH 15, 1833.

No. 1.

THE FARMER.

BALTIMORE, FRIDAY, MARCH 15, 1833.

On presenting the first number of the fifteenth volume of the American Farmer to our subscribers, we would make a few remarks by way of introduction.—The American Farmer has now entered upon the fifteenth year of its existence. It was commenced when there was no other publication devoted to husbandry in the western world, nor any that gave the subject any thing more than a mere passing notice.—For some years it remained the solitary advocate of the agricultural interest, and was viewed by the mass of American cultivators with an askance eye on account of its obtruding its "*book farming*" upon the old routine of our fathers. Nevertheless, it found favor with some, and this continued to increase as its claims to attention became known, until it found its way into every state and territory in the union, and in some states into every county. From its commencement its good effects upon agriculture became visible, and at this time there is not a neighborhood east of the Allegany mountains that does not exhibit monuments to its honor in its improved husbandry.—We feel no delicacy in saying this, because the gentleman who established and conducted it then—and to whose spirited and patriotic genius our country is indebted for all it effected in the improvement of our husbandry—has long since retired from it, and left to other hands the completion of the grand design. As soon as the great advantage of such a journal became apparent, others were established, successively, in the east, in the south, in the north, and in the west, till at this time there is scarcely a state in the union that does not possess a paper chiefly if not exclusively devoted to agricultural affairs. As the American Farmer was from the beginning devoted to *American agriculture*, embracing all sections of our extensive country, and the interests of all in its range, it was of course neither southern, nor northern, nor eastern, nor western, in its designs or partialities. The effect, therefore, of the more local publications, has been to circumscribe the patronage of the American Farmer, as each successively became established, and we are now left with a list of subscribers barely sufficient to pay expenses. The object of these remarks is to solicit of our friends a little exertion on behalf of this publication, in the way of obtaining new subscribers. We feel assured that each present subscriber could easily obtain one new one—some more—and this would render our patronage an object of profitable concern, and also would extend the usefulness of the work. We beg our subscribers to think of this hint, and put it in practice.

STOCKING KNITTING MACHINE.—We have been very much pleased with a little machine for knitting stockings shown to us a day or two ago by Mr. John McMullen, of Birmingham, Huntingdon county, Pa. It occupies about a cubic foot, and is operated upon by turning a crank, which requires no more power or skill than a common hand organ, except when necessary to widen or narrow the stocking a stitch is dropped or added by hand. The machine does the work of six expert knitters, and is very simple. It is superior to the stocking loom, as that requires an apprenticeship to learn to work it, and is not calculated

for families. The present machine can be worked by any intelligent little girl, after a few minutes instruction, and is not costly—fifteen dollars, including the patent right. The machine we saw is best calculated for knitting wool, but we believe it can be readily adapted to cotton, silk, or linen, at pleasure. There are none of the machines for sale, the proprietor only wishing to sell patent rights, except in Pennsylvania. Any further information may be obtained from Mr. McMullen, whose address is given above.

☞ The letter from "*B.*" shall be attended to in our next.

THE COMPASS PLANT.

Mr. SMITH: *Nelson Co. (Ken.) Feb. 17, 1833.*

Inclosed, I send you a few of the seed of a plant, growing in the great prairies of the west. It is called the compass plant by some and by others the rosin weed. It is one of the most extraordinary plants in nature. The name of *compass plant* proceeds from the fact of its leaves, which are very large, rising from the root to the height of from one to two feet, presenting their edges almost invariably to the north and south—and consequently their broadsides to the east and west. This circumstance renders this plant almost an unerring guide to the traveller in cloudy days, who may be caught in those large plains, where, to use an expression sometimes used in those regions, he is out of sight of land—that is of growing timber, whereby to direct his course.

Such is the great uniformity of surface in those extensive prairies, that the most skillful woodsman would be unable to steer his course in a cloudy day, but for the aid of this plant. And the fact of its being found (so far as I have heard) only in those places, where the polarity of its leaves, so to speak, renders it eminently useful to man, seems to present it as one of the strongest proofs of special providence that has been presented to my mind.

The name of *rosin weed*, proceeds from a gum which exudes from its stalk, and dries and hardens in the sun, resembling considerably in appearance, taste and smell, the rosin of the pine—but I should say more pleasant and aromatic. It is quite adhesive, and I was told had been used as a substitute for shoemakers' wax.

The root of this plant somewhat resembles the parsnip, both in size and appearance. When cut in the spring by the ploughshare in turning over the sod, that portion left in the ground, discharges very freely a gummy substance about the consistency of honey, having very much the taste and odor of the gum which exudes from the stalk. The stalk grows to the height of from four to six feet.

Whether something useful might not be extracted from these roots, is I think worthy of experiment. If so, it could be produced in the prairies to any extent. Whether it will grow out of the prairies, has not, so far as I know, been tried. I mean to try it myself this spring—and have supposed a few of the seed would be acceptable to you. They are of last year's growth, sent me by a friend last fall from Missouri.

Very respectfully, THOS. SPEED.

[REMARKS.—From the above description we are entirely unable to identify the "*compass plant*" with any one known to us. The seed seem to belong to the natural order of compositæ, resembling those of

the dahlia somewhat. We should be glad, if any of our friends know the plant, for a more particular account of it.—*Ed. Am. Farmer.*]

THE PALM TREE.—This tree seems particularly intended by Providence for the uncivilized and destitute savage. It affords him a pleasant drink, and, indeed, the common and favorite drink, especially along the coast of Africa. The wine, as the juice is called, is obtained precisely as the juice of the maple is in America for a different purpose; a hole is bored in the trunk of a tree, a spout made of a leaf inserted, and through this the liquor flows into a calabash beneath, which, holding two or three gallons, will probably be filled during the day. It soon assumes a milky appearance, and is generally used in that state; if kept longer, it acquires rather a bitter flavor. The palm tree also afford a valuable oil, of which immense quantities have been heretofore taken off by foreigners, particularly by Liverpool traders. The palm wood is an excellent material in building the simple dwellings of the natives.

(From the Virginia Farmer.)

ROCK-MARL, FOUND IN PRINCE EDWARD.

We understand that Dr. Norton, of Prince Edward, has found upon his farm, an inexhaustible bed of rock-marl. This is certainly a very valuable acquisition to the farming interests of that county. We do sincerely hope that they may freely realize the best effects. From a conversation with a gentleman a few days ago, we doubt not, but that there is an abundance of it in Cumberland, and other counties in middle Virginia. How is this state blessed with mineral wealth? It appears that nature had anticipated her present impoverished situation, and put into her bosom a full restorative. We expect in a few days to receive a communication on this subject, which will, no doubt, be very interesting.

STARCHING.—Some of our female readers would, we presume, like to have us record some of the facts which we now and then pick up in conversation. If they wish to make a brother or a son look a little smart on some particular occasion, they must, after having boiled the starch, and while yet hot, stir a little tallow in with it, or, what is better, a small bit of sperm candle. The linen should be pretty wet when ironed, and the iron hot. Treated in this manner, starched apparel looks much better and keeps clean longer.—*N. F. Farmer.*

SINGULAR SAGACITY OF A PONY.—Mr. Jonathan Gain, of Lumps Farm, in this island, sold a pony of the Shetland breed, which he had had in his possession about seven years, to Mr. Wm. Padwick, of Hayling Island, who immediately took him home. On Mr. Gain going out of his house three mornings after, he found the pony at his gate, having made his escape from his new master, swam across Hayling harbor, and returned without leave or license to his old quarters. The animal whilst crossing the harbor was seen by the preventive men, who, mistaking his errand for a cask of spirits, immediately made after him, when to their astonishment the supposed cask on a sudden landed on the opposite shore, and galloped off without further molestation.—*Portsmouth paper.*

AGRICULTURE.

(From the Southern Agriculturist.)

ESSAY ON ROTATION OF CROPS;

By J. HAMILTON COUPER;

Read before the Union Agricultural Society.

[This excellent essay on the rotation of crops we obtained from Mr. Couper, during our late agricultural excursion into Georgia. It was not originally designed for publication, but having solicited, and obtained a copy, we now have the pleasure of presenting it to our readers. The subject is one of great importance to us, and ought to command the attention of every agriculturist. Circumstances prevented Mr. Couper from extending the essay as far as was originally intended, he has, however, promised us to resume the subject as soon as his leisure will permit.—*Ed. So. Agr.*]

The difference of effect produced on the fertility of the soil, by the spontaneous growth and by the artificial culture of plants, is so strikingly contrasted, as to present itself very forcibly to all observant minds. Where nature is allowed to sow her own seeds and to reap her own harvests, the earth, instead of being impoverished by her vegetable productions, seems at each new effort but to augment that fertility, which is ever presenting to the eye a varied aspect of beauty and fruitfulness. But very different has been the effect in most countries, where man has controlled the productions of the soil, and limited them to those alone which contribute to the gratification of his wants, conveniences and luxuries. Their exhaustion generally follows production, and utter impoverishment would succeed to teeming fertility, were not resort made to benign nature, or to expensive manures, to restore the lost fertility.

Is this contrast the necessary effect of the peculiar character of the plants which have been selected for cultivation? is it owing solely to cultivation; or has it arisen from a vicious system of agriculture, in relation to both? The continued and increasing fertility of some countries, where these plants are most extensively grown; and where cultivation is carried to the greatest perfection, proves that the impaired productiveness of the soil, is not necessarily the result of the two first causes, whatever may be their tendency; and that it is chiefly attributable to the effect of a vicious system.

The great error of this system has been, that man, instead of following the golden maxim of Lord Bacon, of conquering nature by obeying her laws, has endeavored, in opposition to those laws, to force her into a subservience to his own views. Had he observed the changes of vegetation which were spontaneously occurring around him, he would have perceived, that of the seeds of plants, which are scattered with a lavish hand over the earth, those to which the soil and climate were most congenial, and which found the greatest supply of food fitted to their support, obtained the mastery in the contest for existence; and continued to flourish, until having reduced or exhausted those principles of nourishment peculiar to themselves, they abandon the soil to others, to which it still afforded the elements of unimpaired luxuriance. These in their turn, having occupied it for a time, gave way to more successful rivals. Thus the earth, forever occupied by plants, to the growth of which it is best adapted, presents the greatest mass of vegetation, which, under existing circumstances, it is capable of bearing; and by their decayed remains and their ceaseless change, the exhaustion of any principle is soon restored, and the fertility of the soil is preserved unimpaired. Here the seeds of plants are abundantly thrown on the lap of the earth, and unerring nature selects those which it is best fitted to bear.

But such has not been the course pursued by man. Of the plants spontaneously produced by nature, he

has made a selection; and has wisely aimed at the extension of those best adapted to his use. But his want of skill has marred his own wishes. Ignorant of the principles of vegetation, he has consigned to the earth that which it was not fitted to bear; or if at first fitted, his avarice has induced him to continue the cultivation, until it was no longer so. The soil has been tortured to produce what it refused; and it has been refused that which it could produce. Man labored: the earth was impoverished; and scanty products were the precursors of others still more so.

Happily this gloomy result is not the necessary consequence of the cultivation of those plants, which minister most to the comforts of man. The progress of information, and the important discoveries of the laws of vegetation, which scientific research has made, during the last half century, have gradually led to a correction of vicious practices. And the establishment of sound principles in most of the departments of husbandry, now prove, that the cultivator may pursue an uninterrupted succession of useful crops, and at the same time maintain the soil in a state of unimpaired fertility.

This result is mainly attributable to the imitation of the principle of change, which constitutes the great and economical law of vegetable production: an imitation which has led to the most important practice of modern husbandry, the rotation of crops.

I have thought that I could not better fulfil the duty which has devolved upon me, by the appointment of this society to prepare an essay upon some subject connected with agriculture, than by attempting a succinct development of the principles upon which the rotation of crops is founded; to illustrate those principles by the practices of the most celebrated agricultural districts; and to suggest a few hints for a succession of crops for our own country. If in this discussion I am led beyond the legitimate bounds of an essay, I must throw myself on the indulgence of the society, who will, I trust, pardon the trespass on their time, in consideration of the extent and intricacy of the subject, and of its importance in reference to the peculiar deficiencies of our own agriculture.

The problem to be solved by the theory of a rotation of crops is, to ascertain by what combination or succession of crops, the soil may be kept in the highest state of improvement, and at the same time be made to yield the greatest net production, for a series of years.

The first object of the rational cultivator, will be to select the most valuable crops, which the peculiar circumstances of his climate, soil and situation admit of. He will further have reference to his own wants, and the demand which arises from markets.

But when he has ascertained the crops which, under these circumstances, are the most valuable, the soil may not be sufficiently enriched to produce them in the greatest abundance, or if sufficiently fertile, the crops may be of a nature so exhausting, as to have a tendency to impair it. He will, therefore, in order to maintain his land in the highest state of improvement, be under the necessity, either of adopting crops less exhausting; or of cultivating the exhausting crops less frequently; or of supporting the fertility of his soils by manures.

Where extraneous supplies of manures can be obtained, as from a vicinity to towns, mineral manures, marshes, irrigation, &c. a course of exhausting crops may be followed, without impairing the fertility of the soil; and the judicious cultivator will avail himself of these extraordinary means of enrichment. But as these favorable situations are comparatively few, and as the investigation of the question will be simplified, by omitting any allusion to them, it may be assumed as a general principle, that every soil, from its own productions, must be made to maintain its own fertility.

The successful application of this principle, depends upon a knowledge of the manner in which ve-

getables in general, tend to exhaust or enrich the soil; and of the nature more or less exhausting of each vegetable.

Plants do not, by the mere effect of their vegetation, impregnate the earth with any fertilizing principles. Their anchoring influence results entirely from the mechanical action on the soil; the beneficial operation of a peculiar mode of cultivation, during their growth; and the return to the earth of their decayed remains.

As all plants do, to a greater or less degree, subtract alimentary substances from the land in which they grow, were the whole of their vegetation removed from it, all plants would be impoverishing. Their enriching tendency, will depend upon the return to the soil, on their decay, of more of the principles of vegetation, than they have subtracted from it, during their growth.

Were all plants alike in their organization and vegetation, their comparative enriching effects would be in the relative proportion of their vegetation removed from the soil on which they grew, to that returned to it. And to the period of their growth at which it was removed. But this is not the case, for vegetables are found to differ essentially, in their exhausting effects, agreeably to their peculiar character, and to the particular mode of culture which they require.

The food of vegetables is found diffused through the soil; or floating in the atmosphere. And plants derive their nourishment, in part by their roots from the principles contained in the soil on which they are fixed; and in part by their leaves and succulent bark, from the atmosphere which surrounds them.

Vegetables having a system of large, succulent leaves, and much open and tender bark, absorb the greater part of their nourishment from the atmosphere. While those with firm and narrow leaves, and close and hard bark, derive their support chiefly from the soil.

It will be obvious from the enunciation of these principles that, by the cultivation of vegetables with a system of large leaves and tender bark, a greater mass of vegetation can be produced, with a given expenditure of the fertilizing principle of the soil, than by the growth of those with narrow leaves and compact bark, since a greater portion of the nutriment of the former is derived from the atmosphere.

It is further obvious that, as vegetables with a system of large leaves, draw much more of their food from the atmosphere than from the soil, if they be returned wholly, or in greater part, to the soil, it will receive more of the principles of fertility than it has lost; and that their tendency must be eminently enriching. On the contrary, as plants with a system of narrow leaves receive their nourishment principally from the soil, if the greater part of their product be removed from it, that which is restored to the earth is less than what has been taken from it, and their effect will be exhausting.

The different proportions, in which different vegetables derived their nourishment from the soil and atmosphere, is considerably influenced by the changes which they undergo in their organization during their growth. Before the period of flowering, a greater proportion of their nutriment is derived from the atmosphere. But the reverse takes place during the maturing of the seed. The proportion of food derived from the soil while the seeds are ripening, also depends much upon the peculiar character, and the changes which the other parts of the plant undergo at that time. The more oleaginous and farinaceous the seeds, and the greater their weight in comparison with the other parts of the vegetable, the greater is the proportion of nutritive principles furnished by the soil. This is still more increased when the leaves, bark, and other spongy parts of the plant, become dried up about the period of flowering, and the nourishment requisite to the perfecting of the seeds, is necessarily derived entirely through the roots, from the soil.

From the review of these principles of vegetable physiology, we arrive at the practical inference, that by the cultivation of crops with systems of large leaves, the soil is less exhausted, than if it be made to produce those with narrow leaves: that if the broad-leaved plants are cut before the period of flowering, they are still less exhausting, than if allowed to mature their seeds: and that if the product of their vegetation be returned wholly, or in greater part to the soil, they become eminently fertilizing. Hence they have been called ameliorating crops. On the contrary, as narrow-leaved crops are highly exhausting, the more particularly when they are allowed to mature their seeds; and these seeds and much of their other products are removed from the soil, they have been denominated exhausting crops. With a knowledge of these principles, and of the character of the plants which he cultivates, the agriculturist is enabled to maintain a proper degree of fertility in his soil. If his land be poor, he will cultivate more ameliorating and fewer exhausting crops, until it is sufficiently enriched. If sufficiently enriched, he will maintain it in that state by his ameliorating crops, which are a source of manure to restore to the soil, those principles of vegetation which have been subtracted from it by the exhausting crops. This is to be accomplished either, immediately, by plunging in the ameliorating crops; or mediately, by employing them as food for cattle, and applying the products of the farm yard in the form of manure.

This interchange of broad and narrow-leaved crops, constitutes one of the most important principles of a rotation of crops. Its application to practice is, however, to be modified by the circumstances which are about to be mentioned.

We have just seen that vegetables are separated into two classes, in reference to the organs by which they derive their food from the atmosphere. The same utility results from a classification with respect to those by which they take it up from the soil. Hence they have been divided into tap and tuberous, and fibrous rooted plants. The roots of the first class penetrate far into the earth, subtract their nourishment principally at a great depth, and divide the soil by their mechanical action. The latter extend themselves near the surface, draw their food from it, and tend to bind the soil. It results from the different action of these two systems of roots, that their interchange will be mutually advantageous; and that an economy of manure will be obtained by it, for when the surface of the soil becomes exhausted and unable to support the fibrous rooted crop, its substratum may still afford an abundant pasture to plants capable of reaching it, by their tap or tuberous roots.

But independently of the quality in vegetables of withdrawing more or less of their nourishment from the soil, in consequence of the peculiar structure of their leaves and roots, experience has proved that every plant has a habit of vegetation peculiar to itself, which by its action on the soil, after a certain period, renders it unfit to reproduce that particular vegetable, until a restoration has been effected of those peculiar principles of which it has been exhausted. Experience has also proved that, although a soil may be thus exhausted and unfit to produce one vegetable, it may be still in a state highly favorable to the growth of many others. These facts are firmly established by the change of plants which is incessantly renewing and beautifying the vegetable covering of the earth; by the alternation of the trees of our forests, so familiar to us all; by the succession of grasses on meadows; and by the daily observation of all practical agriculturists. But while the fact is confirmed beyond the possibility of doubt, it is to be regretted that this is one of the secrets of vegetation upon which scientific research has shed the least light. In lamenting the want of that clear perception of principles, which is so necessary to the direct and useful application of knowledge, it is, however, satisfactory, that enough has been established to prove that in the

interchange of plants of different habits of vegetation, there is a positive economy of the alimentary principles contained in the soil; and consequently that by it a greater product can be drawn from a given amount of manure, than by the continued culture of the same plant.

The effect of plants in exhausting the soil of those principles peculiarly adapted to their support, will obviously be greater the longer they have been cultivated. And in whatever way those principles are restored, it is evident that the time taken to accomplish it, will bear a ratio to that in which they have been exhausting. It is also evident that, if the recurrence of the same plant, on the same field, proves injurious, the succession of those approaching each other in character will also be so, to an extent, varying with their greater or less affinity.

From these views results one of the leading principles of a rotation of crops that, the return of the same vegetable, of the same field, or of vegetables approaching each other in character, should be removed as far as possible.

By a judicious succession of broad and narrow-leaved crops; of fibrous and tap-rooted plants; and by an interchange of vegetables of different characters, the cultivator will be able to adapt his crops to the actual state of the fertility of his soil; and at the same time, to maintain it in a progressive state of improvement.

But in obtaining this he has not accomplished all that is required. The order of his crops may be such, as not to admit of stirring the earth, and of drawing it up to the growing plant; operations which are absolutely necessary to the eradication of weeds; which permit the free admission into the soil of dew and heat, and of the gases, and finer particles of nourishment which constitute, or are found suspended in the atmosphere; and which while by a minute division of the soil they make it more absorbent of moisture, at the same time prepare it for the more ready escape of whatever is superfluous: operations, in fine, which contribute eminently to the luxuriance of the growing plant, and to the prosperity of subsequent crops; and which have been found to conduce essentially to the preservation of the fertility of the soil.

An attention to these points leads to a selection of such a rotation as will alternate crops which offer facilities in weeding and stirring the soil with others which do not: and to commence with a cleansing crop whenever the land is foul with weeds, or is likely to be made so, by the application of manures containing their seeds.

As some plants require a greater degree of fertility of soil to effect their full development than others; and as they require those principles of fertility to be in different states of preparation, and to a certain extent of different kinds, the cultivator will perceive the necessity of applying his manure to the most exhausting crop; and so to arrange the others, as that they may follow in the most favorable succession. Such a succession, as will prevent that useless expenditure of manure, which results from conveying, at one time, to the plant more than it can consume; and which must, therefore, in great part, be dissipated and lost in the atmosphere: or which takes place, when the manure is in such a state, that its fertilizing principles are brought into operation, at a period too early, or too late, to meet the exigencies of the growing plant.

Such are the principles of the convertible husbandry derived from the laws of vegetation. There are others founded on the economy of labor, of time, and of means.

The practical agriculturist will feel the necessity of making such an arrangement, that the labor of preparing the soil, and sowing, cultivating, harvesting, and getting his crops ready for market, may follow in easy, regular, and economical succession. And that it shall be such, as to require the least expenditure of manure and tillage, which may be consistent with a state of the greatest productiveness.

He will also keep in mind that his profits depend upon the economical employment not only of labor, but of time and space. He will, therefore, leave his land unoccupied by a crop as short a time as possible and increase his products by the frequent introduction of double or secondary crops. To this course, he will be the more strongly impelled, when he reflects, that, animal and vegetable manures, being volatile, are rapidly evaporated into the atmosphere, whenever the surface of the soil, in which they are contained, is exposed to the action of the sun; that this subtraction of the fertility of the soil is greatest, when there are no vegetables to be benefited by it: and that it is, therefore, one of pure loss, unattended by any equivalent or peculiar advantage of immediate production, or of remote amelioration. He will not allow his soil to clothe itself with a spontaneous growth: for then that fertility is expended in useless weeds which might be converted into valuable crops, and the selection of the plants, which should be the result of choice, is left to chance, a chance which is likely to intermingle exhausting with ameliorating vegetables, with salutary grasses, baneful weeds, whose ill effects, from the deposit of their seeds, will extend to subsequent crops.

(To be continued.)

(From the Genesee Farmer.)

ON SUMMER FALLOW: THE USE OF THEM RECOMMENDED.

Marcellus, Jan. 12, 1833.

Pursuing the subject of my preceding essay on the culture of wheat and the use of fallow crops, I come now to the consideration of summer fallows. I approach this subject, as well I may, with great diffidence. It is a subject which, through a long course of years, has employed the ablest pens of two hemispheres, and yet it has not been put at rest. Many important questions in relation to it still remain unsettled.

Some there are, (and it is believed their number is not small,) who object altogether to the practice of summer fallowing. The principal objections are the following: 1st. That summer fallows are not profitable, because they require the use of land two seasons for the production of one crop. 2. That they have an injurious effect upon the soil, by exposing it to the loss of many of its fertilizing properties.

The objections are at least plausible, and worthy of attentive consideration.

It is believed that the husbandry of this country has been, in many respects, misdirected, by yielding an undue respect to the theories and practices of other countries. It should be considered that the disparities between the condition of our husbandry and that of England are very great. There land is every thing, and labor of little account. The annual rent of an acre of good wheat land, in that country, amounts to a considerable sum. A loss of its equivalent is felt as a serious inconvenience. This then is a good reason for rejecting summer fallows in that country. But here the case is quite the reverse. With us, labor is every thing, and land is of little account. The annual rent of an acre of good wheat land, in this section of the country, allowing for rent a sum equal to the interest of its price if sold, would rarely exceed two dollars and fifty cents. This then presents no formidable objection to the practice of summer fallowing. It should be considered also, that the turnip husbandry, which prevails to a vast extent in England, goes far towards superseding, in that country, the use of summer fallows. In this country, especially in this section of it, the turnip husbandry cannot be advantageously adopted. It is a fact well ascertained, that the soil in general of western New York, is not congenial to the turnip crop. If it were, the climate of our country, the length and severity of our winters, and the genius of our husbandry, would present great and weighty objections

to its general introduction. For these reasons, and many others, I conclude that the objection to summer fallowing, which arises from its requiring the use of land two seasons for the production of one crop, is not worthy of great regard.

The second objection is far more subtle, and it involves greater difficulties. This objection is, that summer fallowing injures the soil by exposing it to the winds, and, without shade, to the scorching rays of the sun; and also, that it puts the soil in a situation to lose a valuable portion of its animal and vegetable properties, by putrescence and exhalation.

1st. I admit the fact, that summer fallowing does expose the soil to the agency of winds, by the means of which it suffers some losses. This evil is unavoidable. The objection applies to all sorts of tillage, and to every process by which the soil is pulverized and brought into a light and loose condition. The winds may blow away a portion of the finest and best of its particles.

2d. That the direct rays of the sun, beating upon unshaded ground, has an effect upon it to injure the soil, has not been proved to my satisfaction. I know that many writers have expressed fearful apprehensions of injuries to the soil by the agency of that heavenly luminary, without whose genial and life giving rays no soil could be productive—nothing could grow, and absolute sterility would characterize the whole face of the earth. Although many have expressed such apprehensions, yet no one has, to my knowledge, exhibited any thing in proof of the theory on which they are founded. It has not been proved that the rays of the sun, in whatever manner they come in contact with the soil, communicate poison to it. It is much more rational to suppose, that sun beams, instead of distempering the soil, impart to it health and vigor.

3d. It is admitted that summer fallowing exposes the soil to considerable losses, by hastening the putrefaction and decomposition of the animal and vegetable substances that are contained in it. These substances have their turns, in the course of the season, of being placed, by the operations of tillage, on the surface of the ground. Exposed as they are in that situation to the utmost agency of the atmosphere, they hastily ferment, become putrescent, and undergo decomposition. Their fertilizing properties depart in gases, and ascend into the atmosphere, where they are supposed to be lost. Here, then, we detect one of the most serious objections to summer fallows. But to do justice to the subject, and strike a fair balance, we should count gains as well as losses.

Those putrescent substances which, at one time, are placed on the surface of the ground, are, by the next operations of the plough, turned under, and others take their places. At all times, much the greater portion of these substances is covered beneath the surface. These, in consequence of the frequent agitations, changes of position, and intermixtures to which they are subjected, undergo rapid fermentation, but not so rapid as those that are uncovered. In the mysterious laboratory of nature, the whole mass undergoes a powerful chemical process, and who can tell how much it gains or loses?

It may be supposed, that as these putrescent substances which are covered evolve their gases, the superincumbent soil absorbs at least many of them, and derives from that source permanent fertility. The truth is, that by means of a summer fallow, an intimate intercourse is provided between the soil and the atmosphere. The soil, we know, loses much, and probably it gains much. It may not be easy to decide on which side the balance of advantage or disadvantage lies.

By means of summer fallowing, many substances contained in the soil are brought into action, and become its tributaries, which would otherwise remain inert, and be useless. The soil being frequently agitated and kept in the best situation to receive gifts from the atmosphere, doubtless does receive many

valuable donations from that rich store house. For aught we know, countless vapors, floating in the atmosphere, and replete with substances enriching to the soil, are thus caught, and become the means of its increased strength and fertility.

It may well be supposed that summer fallowing is beneficial to the soil, by separating, pulverizing, and intermixing its particles. Such was the theory of the celebrated JETHRO TULL, who, one hundred years ago, distinguished himself in England as an agriculturist. His theory was, that pulverizing and intermixing the soil were enough, without the aid of manure to keep it perpetually in a good condition for the production of crops. No doubt there was error in his theory, yet experience has abundantly proved, that frequent agitations of the soil, by means of which its particles are broken asunder and intermixed, add much to its strength and productiveness.

After all, it must be confessed that our knowledge on these subjects is very limited. It is not safe to rely on conjectures. What then are the facts in relation to the subject before us? Has it been found that summer fallowing is hurtful to the soil? When was it, and where was it, that a field was known to be injured, and rendered sterile, by the process of summer fallowing?

It will be seen that I am taking the side of summer fallows. On this subject my mind has vacillated. The time was when, trammelled as I was by the theories of British husbandry, I should have given my voice for the total, or almost total, expulsion of summer fallows. By experience and much reflection on the subject, I have been enabled to break the fetters, and now I am satisfied that summer fallowing is harmless as to the soil, and that it is one of the happiest modes of culture that can be practiced in this section of the country. If I mistake not, it is happily adapted to the genius of husbandry in western New York. If the desideratum is to subdue stubborn soils, or to cleanse the ground of foul weeds, no other mode of culture can be employed for either of these purposes to so great advantage as that of the summer fallow.

But while I recommend summer fallows, let it be remembered that I disapprove the style in which they are generally conducted in this country. Summer fallows should be commenced early in the season, that there may be time enough to perform the work in good style. The work should be done in so perfect a manner as entirely to destroy all the grasses and other vegetables that might be growing in the field. All the sods should be dead and rotten in season to be broken into fragments, and the whole surface of the field should be brought to exhibit a specimen of fine cultivation. In ordinary seasons, all this can be done without difficulty. Farmers would gain much by improving the style of their summer fallows, and bringing it to the standard I have now suggested. Advantages greater than many of them are aware of, would result from it, both as to the crop of wheat which is immediately to follow, and the better preparation of the ground for subsequent culture, and the production of other crops. DAN BRADLEY.

(From the Poughkeepsie Journal.)

CORN CROP ACCOUNT.

MR. POTTER: Poughkeepsie, Feb. 3, 1833.
If you think the following account (taken from my *Farm Book*) worthy perusal, it is at your service.
Yours, respectfully, T.

Account of corn crop of 1832—field four acres; sandy loam; corn in hills three feet apart.

Debit.		
96 loads manure at 50 cts. -	-	\$48.00
10 days' carting do. at \$2. -	-	20.00
34 days' ploughing—\$2. -	-	7.00
14 " marking out—\$1 25 -	-	1.88
5 " planting—75 cts. -	-	3.75
9 " hoeing and plastering—75 cts. -	-	6.75

10 cwt. plaster -	-	5.00
6 days' ploughing corn—\$1 25 -	-	7.50
84 " cutting up and stouting—75 cts. -	-	6.37
36 " husking and binding stalks, 75 cts. -	-	27.00
3 " team, carting corn, &c.—\$2. -	-	6.00
2 " two men carting stalks—\$2.75 -	-	5.50
1 bushel seed corn—63 -	-	63
1 " potatoes—37 -	-	37
Pumpkin seed—6 cts. -	-	6

Total expenses, - - - - \$145.81

Credit.

266 bush. corn, at 62½ cts. -	-	\$166.25
10 " potatoes—37½ cts. -	-	3.75
3 loads pumpkins—\$1. -	-	3.00
Stalks, -	-	22.00

\$195.00
Expenses, - - - - - 145.81

Clear profit, - - - - - \$49.19
Equal to the interest of \$175.00 per acre, even after charging the corn with all expenses of manure; it would certainly be fair to charge it with only half, as the succeeding crops will be materially benefited by the manure left unexhausted by the corn, and in case of that deduction, my field has yielded a sum (\$3.19) equal to the interest of \$297.00 per acre.

HORTICULTURE.

CULTURE OF GRAPES.

MR. SMITH: March 7, 1833.

The cultivation of the vine has been a pleasurable employment to me for some years, accompanied with results highly satisfactory; and as my experience principally has been with the delicate foreign varieties for table use, the relation of the mode of culture may, perhaps, be found acceptable to some portion of your readers, especially those who desire this delightful and profitable amusement in yard or garden cultivation. Could the experience of each individual be so obtained, with the particular description of situation, soil, exposure, and varieties of the vine, with the attendant circumstances, much useful information would be thus collected, that could not but be productive of important and valuable advantages. Willing to add my little to the heap, I have drawn up the following observations, being the result of eight years' practice in the propagation and culture of this plant.

I commenced in the spring of 1825, on Fells' Point, in a lot eighty feet square, and in the centre of a square of buildings; the soil composed of mixed earth, clay, tops of commons, oyster shells, and sand; the understratum being argillaceous earth. The varieties were the golden, red, and parsley-leaved Chasselas, Sultan, white sweet-water, Miller's Burgundy, Malaga, Malmsey, with a few other foreign sorts; of the American kinds, the Catawba, Isabella, Bland's Madeira, Schuyllkill Muscadell, and the Vevay grape.—Owing to the difficulty, then, of obtaining cuttings of superior foreign varieties, as there was at that period, in this state, but little general interest upon the subject, I was forced to adopt propagating with but *one bud* to each cutting, and this effect was successfully accomplished by choosing them from the strongest and perfected wood of the preceding year, from vines which had previously borne fruit. They were embedded in flower pots and boxes of earth; the side shoots removed, and the single branch trained perpendicularly. The following autumn, or in the spring, the roots were planted where intended with five, if practicable *ten buds* below the surface of the earth.—Those planted after this manner are far more vigorous and constant bearers, than the common mode of a cutting with four or five buds; but should the first season not have supplied the desired number, I more deeply

* Vines very luxuriant, but the crop almost nothing.

planted, kept the holes open, and filled up as they progressed in growth. This I would strongly insist upon, as it is well known the vine is fond of water, and will search it at great depths; and the more vigorous and directly perpendicular the tap root, correspondingly, will be the vigor and health of the vine.

Pruning is an operation of considerable importance to the healthful economy of the plant, but upon which no determinate and unalterable rules can be given.—We know plants have certain habits, which are greatly influenced by soil and cultivation, and which can only advantageously be understood by close remark and practice. And in no instance is this more forcibly illustrated, than in the effects consequent on this operation upon the vine. My observations lead me to the conclusion, that the Chasselas and some other foreign varieties should be cut close, and not permitted to bear fruit until the fourth year; this observance will greatly strengthen the root and perfect the future constitution and fruit-bearing wood. I usually prune the last week in February, or the first in March, but am not particular about it, provided it be done immediately before the rising of the sap.—The first season reduce to one bud; the second to two; the third two buds to each branch; the fourth year three; if intended to cover high arbors, at this period all the side buds should be taken close off, except the *two superior ones* to each branch, which are left to form a head for the future tree and the complete covering of the arbor. After this time, by keeping in view the age, vigor, and health, there can be no difficulty with attention to prune judiciously and correctly. There is, however, in the *trimming* of the *Sultana*, one exception to the general and peculiar advantages of close pruning. This truly beautiful and exquisitely delicious grape, is now nearly excluded from the yards and gardens of this city, and many places elsewhere in consequence of its unproductiveness. It is a vine of rapid and large growth, with difficulty restrained to its proper place, and giving itself mostly to the formation of new wood. It offers to the delighted amateur, in early summer, the fairest prospect of an abundant vintage, but before the expiration of a few weeks, he is vexed and disappointed at the gradual and constant fall of most every berry. Were it not for this habit of abortiveness, it would, certainly, be one of the finest table fruits in this or any other country; possessing every requisite to make it such; the vine is hardy, beautiful; the clusters large, and the fruit seedless, melting and delicious.—But notwithstanding this fault, I have persevered with it, and am satisfied that by adopting the subsequent mode of culture, we may obviate this disagreeable circumstance. Having observed its general proneness to the rapid development of new wood, which having the effect to perish the fruit, I made choice of the *first cuttings* from *healthy fruit-bearing vines*, (none others should be used,) and planted and pruned as above directed. The *fourth year* the vines were trimmed down to two or three buds, with the exception of *one branch*—two if very vigorous; and left their *entire length*, and trained to the trellis or arbor, *serpentine* or spirally. Attention being used to keep off the side shoots, particularly beneath the clusters, and at the *setting* or formation of the fruit, the wood of this season to be *lopped* to five or eight buds above the bunches. The effect of this procedure will be to check the rapid expenditure of the juices in the formation of wood and foliage, and to direct them into the racemes to perfect and mature the fruit. By pursuing the said principles of cultivation with this particular variety, I have never been without a good proportion of its fruit, some years as great a quantity by weight as one hundred to one hundred and twenty-five pounds from *five* five and six year old vines; and I cannot perceive why others should not have the same equal results by adopting the like course of management.

Some individuals contend that we cannot succeed in this country with the foreign grapes, particularly for the table, unless in small yard or garden enclou-

tures; and that our indigenous varieties are sufficiently good and nice for such purposes, and will and should supersede those of foreign importation. I wish it were so; but I must most respectfully beg leave, through my observations and experience to dissent from these opinions. I am, very probably, as greatly pleased at the development of the many resources of my country, and as fond to acknowledge them as any other person, and can eat an American grape with as good a zest; but I say *sum cuique*. I judge in point of excellency and quality for table use, that we have not as yet been fortunate in discovering one native, and I have not been unmindful or inattentive to them, that can, or ever will compete with a few grown in this country of exotic origin. And those few, too, with very little extra trouble, can and have been reared in field inclosures. I know that the Chasselas, both golden and red; the white Muscadell, and the white sweet water, have been successfully bearing fruit for some years in field culture in St. Mary's county, not half a mile from the Chesapeake shore; moreover, I know, there are very few farms around Baltimore, but where the common white sweet water has lived, flourished, and borne fruit abundantly for years. These facts are assuredly, strikingly convincing, that we may depend upon the choice of foreign vines for the supply of our markets with this important and useful fruit. As for the manufacture of wine, we are all satisfied from the results of our experiments, that we shall have to depend upon those of our own soil, and as the numbers are yearly increasing, there can be no doubt of every wished for success.

J. C. S. MONKUR.

(From the Maysville (Ky.) Eagle.)

CULTURE OF YELLOW LOCUST.

Dear Sir,—I perceive in your last paper an inquiry as to the manner in which the seed of the yellow locust can be made to vegetate. Concurring with your correspondent as to the importance of our farmers turning their attention to the cultivation of timber to supply the place of that which is rapidly consuming and annually becoming more scarce, and having some experience on the subject, I take the liberty of addressing you this note.

The seed of the yellow locust may be readily prepared for vegetation by the following simple process. Place the seed, three days before you intend to plant it, in a tight vessel, and pour over it a sufficient quantity of boiling water to cover the seed, and permit the water to remain on the seed twenty-four hours—at the expiration of that time, drain off the water, and again pour on boiling water as before, suffering it to remain on the seed as in the first instance, twenty-four hours. At the expiration of this period, again drain off the water, and pour boiling water for the third time, suffering it to remain as before, when the seed should be planted before it becomes dry.

After having been thus exposed to the action of boiling water for three successive days, it will be seen that the outer covering of the seed will, pretty generally, have been burst, and it will now readily vegetate.

I would recommend that they be planted like corn, in squares five or six feet apart, that they may be readily cultivated with the plough, as they must be for the first summer. The seed should be planted about the 20th or 25th of April. If planted earlier, there will be some risk of the young plants being injured by very severe frosts—light frosts will not injure them. Two or three plants in a hill are enough, but as some of the seeds may not be good, or so completely freed from the resinous matter which prevents the moisture from penetrating them, I would recommend that six or eight seeds be planted in a hill. If too many come up, they can easily be thinned when hoeing them, but two or three should be left standing in a hill to guard against accidents, and to prevent them from branching too much. As the plants are of

slow growth, when young, care must be taken to prevent the weeds from smothering them. New ground, or grass land is much the best for the growth of locust seed, as these produce but few weeds. The ground in which the seeds are planted should be carefully cultivated, and kept free from weeds during the first summer. In the month of September the ground may be sowed with timothy seed, when no farther care will be requisite except to keep a good fence around the young plants to protect them from stock.

Cattle are very fond of the leaves and tender branches of the locust, in the spring of the year, and are very destructive to the young growth, if not protected by good fences, until they become so large that cattle cannot bend them down. Sheep will also bark them, when young, during the winter and early spring months, but are not apt to injure them, after they can get a plenty of pasture. Great care should therefore be taken to protect them from stock until they attain a sufficient size to place them out of danger.

There is another method of cultivating the yellow locust, more convenient and rather more expeditious than that described above, when circumstances will permit a resort to it. I have practised this latter method with considerable success, and have now growing on my plantation not much short of two thousand thrifty young locusts, of various ages. The plan is this. I select a place where there are a number of locust trees, scattered over a piece of ground suitable for the purpose, and clear off all the timber except the locust, and cultivate the ground in some crop that will come off the ground early, say tobacco or pumpkins. When the crop comes off in the fall, the ground is prepared for timothy, and sowed in time to get a good set. The ensuing spring I cut down all the locusts growing on the ground, removing the brush, &c. The young locusts will now spring up in great numbers. The young timothy will not at all impede their growth, and will yet cover the ground sufficiently to prevent the growth of weeds. No further care will be requisite but to protect the young growth from stock, till it is sufficiently large to be out of danger. In a few years the young locusts will be so large, that calves and young colts may be safely pastured among them, especially if not put in until the grass gets a good set in the spring. In the mean time, if there are any spaces, not occupied by the young locusts, they may be moved. If the locusts put up too thick, they will need no thinning, as the most thrifty will soon overtop those that are not so much so; when the less thrifty ones will die, and make room for the others. Nor do they require any trimming. Growing in clusters they shoot up almost without branching, or if they put forth branches, they are small, and soon die and drop off.

I have locusts growing on my plantation both from the seed and from the roots of those cut down, as above directed. I prefer the latter method, when circumstances will admit of it, because attended with less trouble, and the growth is somewhat more rapid than from the seed. But where there is no situation suitable for this mode of cultivation, the other may be resorted to with great success.

If you suppose this note will at all promote the views of your correspondent, you are at liberty to make such use of it as you may think proper.

Yours, respectfully, A. B.

EATON'S MANUAL OF BOTANY.—Notice is given in the Albany papers that the sixth edition of this work is now in press in that city, and will soon be published. In this edition the genera are arranged under the Linnaean artificial system, and then repeated under the natural method, with the improvements of Brown, De Candolle, Lindley and others. The etymologies and accentuation of all the genera are given, and the plants of the northwestern lakes, of the Rocky mountains, &c. are added from Hooker, Douglass, Drummond, Golsie, Richardson and others, and the new species of De Candolle, &c.

RURAL ECONOMY.

(From the Southern Agriculturist.)

A SUCCESSFUL METHOD OF RAISING DUCKS.

Charleston, February, 1853.

Believing it to be the duty of every individual to contribute for the benefit of society, any information he may possess, however small, and on subjects ever so humble; and having for several years past been in the habit of seeking recreation during those hours which were not devoted to so vexatious studies and labors, in a variety of experiments on subjects of natural history, I propose giving you the result of some experiments in raising ducks, which were carried on during a number of years, and which finally eventuated in complete success.

It is sometimes beneficial to examine the causes of our failures, and it affords me pleasure at this moment in retracing the steps by which, after many disappointments, I gradually accomplished the objects to which my inquiries and experiments were directed. As an account of the process by which I arrived at these successful results, may not be uninteresting to those of your readers who devote themselves to rural pursuits, and who pride themselves on having a well stocked poultry-yard, I hope it may be no tax upon their time and patience, if I go somewhat into detail.

During many years I was struck with the general want of success which attended the raising of this species of poultry. Not one-sixth of the young were ever raised—they appeared to be subject to innumerable diseases. Those that escaped were stunted in their growth and did not arrive at full size till they were many months old. The general complaint among farmers and planters was, that this the most valuable of our poultry was a puny bird hard to raise and subject to many diseases. They could raise fowls and even turkeys, but there was no certainty with regard to the duck.

Desirous of investigating the causes of a failure in raising a bird which in its wild state is very hardy—which, although exposed to all the vicissitudes of the weather, raises large broods of young, I procured several ducks determined to pursue my experiments in various ways till I should either be successful or be satisfied that in a state of domestication, there existed obstacles to their successful rearing which no foresight or care could prevent.

At first I adopted the usual mode of giving them access to as great a body of water as I could provide for them in the yard. I therefore had an artificial pond made near their coops, to which they could resort as often as they chose; here they amused themselves at all hours of the day, in dabbling around the edges of the pool, and in swimming and diving in the water; but they did not grow—they were subject to cramps and fits, and one after another died, until I began to think that water was not their proper element. I varied their food—gave them rice-flour, corn-grist, boiled potatoes, hominy, bran, and many kinds of vegetable food, but with the same results—and at a hundred young that were hatched, I scarcely raised a dozen. I then began to mix with their food various medicinal herbs, believing that this might correct some deleterious properties of their food, but it was to no avail. I next procured the different varieties of ducks for breed, thinking that perhaps one kind might be better suited to the climate and the confinements of the poultry yard than another; but I was soon convinced that my want of success was not owing to my breed of ducks. Several years passed away and left me pretty much where I began, and I was almost ready to abandon any further attempts at raising the duck.

The thought at last occurred to me that in the food with which we usually fed this species of poultry, we departed widely from nature, and that, although the old ducks in their wild state fed on rice and the

seeds of various grasses that are found along the edges of the rivers, brooks, and ponds, yet, that at the spring of the year when the young wild ducks are hatched there are few seeds ripe, and it is questionable whether at that early age they feed at all upon grain or seeds. There appears in the digestive organs of these young birds something unsuited to this kind of food—it passes through them with out affording much nourishment. I had ascertained by dissection that their gizzards were filled not with vegetable food, but with the fragments of small craw-fish, worms and various aquatic insects, as well as the spawn of fishes, and I determined in the following year to try the effects of animal food. In due time my young ducks were hatched, beef was given them at first, after having been chopped very fine; this they devoured greedily and eat it in preference to all kinds of vegetable food. The effect upon their health and growth was immediate and surprising! They appeared to grow faster than any other poultry—in a few weeks they were out of danger, and in a few months fit for the table. As beef was expensive I tried cheaper kinds of food, such as the hoes of animals, crabs, fishes, &c. The result was equally favorable. I was now satisfied that in the article of food the end is attained by simply following nature and giving the young ducks animal food.

But although my experiment was thus far favorable, I found that many of my young ducks died after having been suffered to go in the dews and water, and that after many showers of rain they became thoroughly wet, and that when showers were succeeded by hot suns, they were subject to a disease of some apopleptic character, or a *coup de soleil* which killed numbers. Here I was much puzzled. I had succeeded in one instance by following nature, but I found that I could not carry my theory through, and that water affected the domesticated duck very differently from what it did the same bird in its wild state. The fact was not unknown to me that the down of young wild ducks is almost impervious to water: they are exposed to dews and rains—they dive to the bottom of pools and streams, and live in the water; yet they always keep dry—an oleagenous substance is spread over their feathers, from which the water glides off instantaneously and leaves the bird dry during all weathers. Not so with the young of the domesticated duck. Owing, either to the confinement of numbers in a small space, where their down becomes ruffled and displaced, or to their not being able to procure that kind of food which in the wild state is favorable to the secretion of that peculiar oil which is found contained in the glands of birds, and which serves to lubricate their feathers and protect them from the wet, the down of the young tame duck soon becomes thoroughly wet, and when this is once the case, it is subject to various diseases and is difficult to raise. To accommodate the young duck to that artificial state into which it had been thrown by domestication, I found it necessary to adopt some mode by which during the first few weeks of its life, the only time in which it requires much care it might be preserved from the effects of that element, which in its native state is almost its only residence, and furnish the means of its subsistence. A little reflection enabled me to guard against the inconveniences and dangers which result from this state of domestication. I had my coops built pretty large and tightly shingled, so as to be impervious to water. The young ducks were not let out in the morning dews till the sun had dried the grass, and the vessels in which their water was placed were raised over, so that they could drink by inserting their bills between these little railings, but were prevented from getting into the water. After following these simple directions with regard to food and shelter, I found that by a little attention of a servant, I could supply my table with ducks the whole year round—that I seldom lost one in twenty, and that they were free from all diseases. I raised from one hundred to three hundred

ducks per year, and now found that they were the easiest of all poultry to raise. I communicated the result of my experiments to my friends. Those of them who had the disposition—the patience and industry followed my directions, and in every instance met with the same success—I have their assurance, that they can now raise ducks in any numbers, and some of them have for the last two or three years supplied our markets with from three to five hundred ducks of the largest size and finest flavor.

After having carried my readers through this, perhaps to them, tedious detail of experiments which cost me much time and attention, but for which I was more than repaid by the successful result, I shall now proceed to give, under different heads, such simple directions as will enable our planters and farmers to supply their tables with this kind of poultry, which might be an object to those who are in the habit of supplying our markets.

1. *The species and varieties of ducks best adapted to the purpose of breeding.*—The only two species of ducks that are raised in this country are what are commonly called the English duck and the Muscovy duck. The English duck is a descendant of the wild duck that visits us every winter in such numbers called the Mallard (*Anas boschas*) is found also in Europe, and breeds in England, although not the largest it is certainly among the finest flavored ducks in the world. The flavor of the famous canvass-back duck (*Anas rallisneria*) that is found so numerous in the Chesapeake, and more recently in the Santee, and at the mouth of the Savannah river, is no doubt superior to it, but it is supposed that this is owing to the peculiar kind of food on which that bird feeds, believed to be the *Vallisneria Americana*—and that were it fed on common food its flavor would not be superior.

The English duck, which is so common in our yards, has from its long domestication, run into a number of varieties, which differ so much from each other as to appear like different species; they are of different sizes—of a variety of colors, and some are tufted. The variety to which I have usually given the preference, goes by the common name of the Madagascar duck, is distinguished by its being of the largest size—having a pretty long neck and almost invariably a light streak above the eyes, and usually a small streak extending from the lower part of the upper mandible to below the eye.

The Muscovy duck (*Anas Moschata*) is another duck more recently introduced, but which is now very common, and is well deserving a place in our poultry-yards. It was formerly, by most writers, considered as coming from the eastern continent, but is now well ascertained to be a native of South America. This duck, in our southern climate is, perhaps, more hardy than the other—sets more steady on its eggs, and lays in the spring and fall. A mongrel breed between this species and the English duck is easily produced, and has become very common; but these, though they are good layers, are unable to propagate their species.

There are other species of ducks, which the curious in these matters have partially succeeded in domesticating. I once saw a fine flock of the Gadwall duck, (*Anas strepera*), which an individual, in the upper parts of the State of New York, had succeeded in raising from ducks which he had captured, and which he freely in his yard, and made no attempts at flying away. Our beautiful summer duck (*Anas sponsa*) breeds freely in some parts of France and in the Zoological Garden in England. But it is very probable that the two species above mentioned are as well adapted to our purposes as any other, and that, for many years, they will be the only ones which will be generally kept in our poultry yards. One drake will answer for five or six ducks. Where mongrels are to be bred, place in a separate yard, one Muscovy drake to four English ducks.

2. *The best mode of procuring an abundance of*

Eggs.—When ducks are raised in the country and have access to rice fields, ditches, ponds, and the borders of rivers, they find food best suited to them and generally lay early and freely. But where they are necessarily kept in yards, and do not possess the above advantages, it will be necessary to adapt their food to their situation. A mixture of any kind of animal food with their rice flour, corn meal or grist, given them regularly and plentifully three times a day, will enable you to procure a great abundance of eggs; where this is neglected, your English ducks will lay but sparingly. I have observed that animal food is not so necessary to the Muscovy duck, but that they will generally lay pretty freely on being fed on grain alone.

3. **Setting and hatching the Eggs.**—The English duck, although a good layer, is very careless about hatching its eggs until late in the season. I have invariably used the common hen for that purpose; and when the young ducks are removed as soon as they are dry, their foster parent will set again on other eggs; and I have thus known a single fowl to bring out three, and even four broods of young ducks in succession. In that case, she should be repaid for her faithfulness by being richly fed. The young ducklings, in this climate, leave the shell on the twenty-sixth day. The Muscovy set a few days longer. A fowl of a tolerable size will cover from thirteen to fifteen eggs. After the eggs have been four or five days under the hen, you may, in the evening, examine the eggs by the light of a candle or lamp. Place the eggs longitudinally between the fore finger and thumb. If the egg be likely to hatch, it will be of a dark color, with streaks of red frequently perceptible; and the cavity on the thick end will be somewhat enlarged and transparent. If it be a clear egg, it will be wholly transparent, and it ought to be removed at once; and it it have not been kept too long in the nest, it is still fit for use. In this way, when several hens have been set nearly at the same time, it will frequently be practicable to remove a sufficient number of clear eggs, so as to place a fresh setting of eggs under one or more of them. The Muscovy duck sets faithfully, and may as well be permitted to hatch her own young.

4. **Method of destroying Fowl Lice.**—The insects which infest the setting hens may be easily destroyed by thoroughly sprinkling the nest, and wetting the fowl, even to the skin, with a strong decoction, made by pouring hot water on a good handful of common leaf tobacco, mixed when cold with a table-spoonful of spirits of turpentine, and double the quantity of gunpowder. It will be well, also, occasionally to take away their old nest and make a new one of fresh hay or straw.

5. **Duck Coops, Food, and manner of rearing the Young.**—Let your coop be made pretty large; say three or four feet in length and three in depth. Let it be well shingled, so as to exclude all water, and have a good pitch towards the front. Let it be light on three sides and barred in front, with a slide below the lower bar, so as to retain the ducks in unfavorable weather. A space of ten or twelve feet square, formed of common boards set up edgewise, will, when you have not much room in your yard, suffice for fifty ducks. Keep making coops in proportion as your ducks increase in numbers, and endeavor to keep the different sizes separated. The first brood, early in the spring, requires, for a few days, the warmth of the hen's body; and she should not be made to take care of more than twenty or thirty. A little later in the season, the young that are then hatched do not require the services of their foster mother, and may from the beginning be placed in a coop by themselves, to the number of fifty. Young Muscovy ducks may be treated in the same way; and they and the mongrels, and English ducks, may all be indiscriminately reared together.

As soon as your young ducks are hatched, let them be placed together, for a few hours, in a basket containing some warm inside lining; and when they have sufficient strength, place them with the hen in the coop. Feed them with meat, or animal food of any

kind, chopped fine with a common chopping knife. For convenience, I have usually had it boiled. A little rice flour or corn meal may be mixed with it, and the latter may be increased, if you have but little meat. Let this be continued for three weeks, and they are out of danger and can be raised on any kind of food. Still it is to be observed, that ducks will in all cases thrive better on animal food, and where this can be conveniently obtained, it may as well be given them. Those planters who live near our sea coast, by running a tight board fence across any small branch of salt water, and placing in the centre a fish-trap made of laths, can easily procure a sufficient quantity of fishes and crabs to feed all their young poultry. A man with a cast net, could in half an hour do the same. I have known persons, in the interior of the country, substitute squirrels, rabbits, and even venison; and one gentleman fed his young ducks on the flesh of alligators, thus rendering that which was a nuisance, subservient to his profit. When your young ducks begin to be tolerably feathered on the sides, which will be in five or six weeks, they may then be turned into the common poultry yard—always bearing in mind, that those which are best fed and obtain most animal food thrive the fastest.

I have not treated of diseases to which ducks are subject; since, by the above treatment, I have generally found them healthy.

As this is a long essay, and may be too great a tax on your readers to peruse, I would give, in a single line, the substance of my directions for the successful rearing of young ducks:

Give them animal food and keep them dry.

EXPERIMENTER.

(From the Farmers' Chronicle.)

FENCES.

It is a most erring policy, that induces farmers under the name and notion of *economy*, to inclose their grounds with temporary and defective fences. It is in truth the very worst of economy, or rather the very reverse of economy. It would be well for those who feel inclined to negligence, or to be governed by the "do-for-the-present" doctrine, to open an account of *debt* and *credit* with their fences for a few years; and if that should not cure them, they might be given up as incurable.

Perhaps some of our readers might be edified by a sight of such an account at any rate, if it should not happen to suit their own experience, it may give them some idea of this sort of *Book-keeping*: and here it is.

"Cornfield FENCE, Dr.

To corn destroyed by horses, cattle and hogs at different times, supposed one hundred bushels, say \$25.

To time lost in stopping *hog-holes*, repairing fences and mending *water-gaps*, say six days, *in harvest*—\$5.

To wounding one of the plough horses, in breaking over the fence, by which his services were lost for ten days when they were most wanted, say \$5.

To price of a hog of my neighbor Hodge, for which I had to pay, having *dogged* it in my cornfield, so that it died, \$3.

To time lost in attending a law suit about said hog, and costs of suit, \$5.

To loss of a valuable dog which I supposed Hodge had killed, in revenge for the killing of his hog by said dog, but which I could not prove, \$5.

To perpetual loss of Hodge's friendship, which had been steadfast for twenty years—amount not known.

To the spoiling of my young horses, Smith's cattle and Hodge's hogs, so that I shall never be able to fence them out effectually hereafter—loss not known.

To keeping me in *bad humor*, *fretted* and *crabbed* nearly all summer—damage incalculable.

Total, exclusive of the three last items, \$48.00
Credit,

By five hundred rails, the number wanting to make the fence good; but which as they must be finished next spring, are only saved for one year, su

that the interest on their cost is the only saving—cost \$10—interest at 10 per cent. is \$1.00.

By labor which would have been required to put the fence in good condition; say \$10 at most, but which having still to be done, is only entitled to a credit to the amount of interest as in the former case, \$1.00

Total, \$2.00

Balance against bad fences, \$16.00

And the said debtor (bad fences) being utterly *insolvent*, the whole amount is irreparably lost: except, that it has taught a lesson which may be useful hereafter.

SYLVESTER SLOVEN.

What came to pass in the case of neighbor Sloven, has happened to many others, and will continue to happen, until proper attention shall be paid to what should be a farmer's first concern, good enclosures.—Nothing can be more *unbearably* provoking, than after having toiled all the season to raise a good crop, then to have the whole destroyed in a single night.

But besides the security and actual gain of good fences, nothing more than this contributes to the neatness and good appearance of a farm, and without this it is impossible to do away a repulsive and condemning aspect of slovenliness, which indicates any thing rather than good husbandry.

But if he is censurable who neglects the enclosures about his fields, meadows and pasture grounds, what shall we say of him whose very garden—a spot which should of all others be *sacred* and secure, is constantly "profaned by *vandal* swine," and suffered to be trodden down by the "beasts of the field?" If he attempt his defence by saying there is nothing in his garden worth protecting, we say this too is his fault, and no less a one than the other. It is like making *drunkenness* excuse *theft*.

By the way, the subject of neatness, taste and utility in family gardens, deserves a fuller notice, and shall ere long have a full chapter. In the mean time let us improve the leisure of this winter in preparing to make all our enclosures substantial and secure before the vernal planting comes about.

(From the Genesee (Vt.) Farmer.)

TO CURE WOUNDS ON HORSES AND CATTLE.

As there are many useful receipts hidden from the public for the sake of speculation in a small way, by many who would be thought something of in the world, I am induced to lay before the public a receipt for making *King of Oil*, so called, which perhaps excels any other for the cure of wounds on horses or cattle, and which has long been kept by a few only in the dark. Feeling a desire to contribute to the good of the public, but more especially to the Farmers of Genesee, I send you the following very valuable receipt for publication:—1 ounce of green copperas, 2 ounces of white vitriol, 2 ounces of common salt, 2 ounces of linseed oil, 3 ounces of West India molasses. Boil over a slow fire fifteen minutes in a pint of urine; when almost cold, add one ounce of oil of vitriol, and four ounces of spirits of turpentine. Apply it to the wound with a quill or feather, which will immediately set the sore to running, and perform a perfect cure. Yours respectfully,

STEPHEN PALMER.

LEVEL ROADS.—Agricultural writers say that a road perfectly level is not always the best for the horses. Slight and short alternations of rising and falling in the road are serviceable to the horses, provided the drivers are skillful. By these variations the lungs and muscles of the horses are relieved. This is explained on the principle that constant exercise of any of the muscular powers tends to exhaust. Consequently, on a road perfectly level, the same set of muscles are unremittingly exercised; but if there are some descents and ascents, these are either entirely or partially relieved and others brought into action.—N. Y. Farmer.

LANCASHIRE GOOSEBERRY PLANTS.

Just received from England the following choice assortment of the celebrated Lancashire Gooseberry Plants, which are offered to the public with confidence in their superior quality, their genuineness, and fine condition. They will be packed so as to be carried safely any distance; but those that have to go far would better be ordered without delay. The following is a list of twenty-seven kinds:

WHITE FAIR.—Capper's Bonny Lass, Boardman's Smiling Beauty, Holden's White Muslin, Sampson's Queen Ann, Vates' Thrasher, Leigh's Toper.

YELLOW OR AMBER.—Nelson's Waves, Hill's Royal Sovereign, Weedham's Delight, Large Golden Queen, Forbes' Golden Eagle, Sandford British Favorite.

RED.—Walker's Bank of England, Kirsham's Fairmaid, Jolly Minor, Dean's Glory of England, Chadwick's Sportsman, Boardman's British Hero, Boardman's Prince Regent, Fletcher's Crown Regent, Milling's Crown Bob, Eckley's Jolly Printer, Bell's Glorious, Bratherton's Overall.

GREEN.—Hopley's Shannon, Parkinson's Laurel, Allan's Glory of Katelyll.

These plants have been carefully selected from the best sources by a competent person, and are truly fine.

Prices.—Several of these varieties are sold from the gardens at from 50 cents to \$1 per plant, (they are all superior kinds,) but I offer them as follows:

Purchasers may select at 40 cents each, or thirteen plants for \$5. When the selection is left to us we will send three plants for \$1, or sixteen for \$5. The number of each kind is very limited.

BUFFALO BERRY TREE OR SHEPHERDIA OF THE ROCKY MOUNTAINS.

When our friends send to us for Gooseberry Plants we can very conveniently pack with them one or more of these truly splendid trees, which, when in bearing, are literally loaded with delicious red berries, resembling the Antwerp Currant, and set as thickly on every twig as kernels of corn on the ear. Price \$1 each.

ANTWERP RASPBERRY AND CURRANT BUSHES;—GENUINE.

Just received a few plants of the Red Antwerp Raspberry, best kind, at 25 cents each, or \$2.50 per dozen. Common kind usually known by this name, and bearing fine fruit, 12½ cents each, \$1.25 per dozen, or \$5 per hundred.

Genuine Antwerp or Large Dutch Currants, 25 cents each, or \$2.50 per dozen.

Address I. I. HITCHCOCK.

American Farmer Office and Seed Store.

GRAPEVINES AND CUTTINGS.

For sale at the American Farmer Office and Seed Store, the following, which can be sent safely any distance:

ROOTED VINES.

Herbemont's Madeira, two years old, 33 cents each, \$3.30 per dozen, or \$25 per hundred.

Isabella, very fine roots, two years old, 37½ cts. each, or \$4.00 per dozen.

White Scuppernon, one year old 25 cents each, or \$2.50 per dozen.

CUTTINGS.

Cunningham, finest native grape, both for wine and table, 12½ cents each, \$1.25 per dozen, or \$8 per hundred.

Woodson, very fine do. do. same price.

[For description of these, see American Farmer, Vol. xiv. No. 33.]

Norton's Virginia Seedling, fine, same price.

Cuttings of the Isabella, Muscadell, and Golden Chaselas, 50 cents per dozen. I. I. HITCHCOCK.

HERBEMONT ON THE VINE AND WINE MAKING

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States. By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents.

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at \$1 per bushel.

I. I. HITCHCOCK,

American Farmer Office and Seed Store.

FRESH GARDEN SEEDS—NEW STOCK.

I am now receiving from Europe my supply of those Garden Seeds, which it is necessary to import, which together with those of my own raising, and other American Seeds, make my assortment one of the most complete ever offered in this market.

With regard to the quality of the seeds I offer, I can only say I am confident they are good—perfectly so, and I am fully aware that this circumstance is of far more importance to myself than to any of my customers. It is under this conviction that I offer my present stock to the public.

I. I. HITCHCOCK,

American Farmer Office and Seed Store.

SILKWORM EGGS

For sale at the American Farmer Office and Seed Store, at \$1 per thousand. They can be sent safely by mail if ordered immediately, before the weather becomes warm.

I. I. HITCHCOCK.

AGRICULTURAL IMPLEMENT AND SEED STORE.

J. S. EASTMAN, No. 36 west Pratt-st. keeps constantly on hand a supply of his Patent Cylindrical Straw Cutters of the various sizes, which he will warrant to cut as much, according to their size, and to be decidedly superior in every respect to any similar machine made in this country.

Also, very superior Rag Cutters, for the use of Paper Mills.

Gideon Davis' Improved Patent Ploughs, of all sizes, with wrought and cast shares, and all kinds of castings for those ploughs by the piece or by the ton, as likewise for horse powers, on as reasonable terms as can be had elsewhere.

Wheat Fans, Corn Shellers, Threshing Machines, Harrows, Cultivators, &c. Likewise superior Cast Steel Axes, Hay and Manure Forks, and Scythe Snaths at wholesale and retail. Shovels, Spades, Hoes, &c. &c. and all repairs done at short notice.

Field and Garden Seeds. Such Grass Seeds as are in market will be kept for sale. My assortment of Garden Seeds is not so extensive as advertised by some, but such as I shall offer for sale may be relied on as genuine. The following I could furnish at wholesale, viz: Superior Early York Cabbage, and Long Scarlet Radish Seeds, and Early Frame Peas, the latter raised by Richard Cromwell, Esq.

REMOVAL.

SINCLAIR & MOORE have removed their AGRICULTURAL REPOSITORY to the CORNER OF PRATT AND LIGHT STREETS, HEAD OF THE BASIN, where they offer for sale a general assortment of IMPLEMENTS, FEEDS, FRUIT TREES, &c. &c.

Feb. 22.

SINCLAIR AND MOORE'S NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of Hardy Rose Bushes, (among which is the much admired Greville,) double Altheas, Honeysuckles, Cornus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Alantins, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets. Feb. 22.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—The market continues without material change. Holders of flour are more firm at our rates, and sales have been made at our quotations. Howard street flour from wagons is selling at \$5 12½. Wheat has advanced a few cents in consequence of the scarcity.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Line yellow, 18.00 a 26.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 81 hlds. Md.: and 23 hlds. Ohio—total 104 hlds.

FLOUR—best white wheat family \$6.75 a 7.25; super Howard-street, — a 5.25; city mills, 5.25 a —; city mills extra 5.25 a —;—CORN MEAL bbl 3 50;—GRAIN, best red wheat, 1.05 a 1.08; white do 1.05 a 1.10;—CORN, white, 55 a 58, yellow, 55 a 58;—Rye, 68 a —;—OATS, 40 a 41.—BEANS, 75 a 80.—PEAS, 65 a 70.—CLOVER-SEED 8.00 a —.—TIMOTHY, — a —.—ORCHARD GRASS 2.00 a 2.25.—Tall Meadow Oat Grass 2.00 a 2.50.—Herd's, 75 a 87½.—Lucerne — a 37½ lb.—BARLEY,—FLAXSEED 1.50 a 1.62.—Cotton Va. 10 a 12—Lou. 12 a 13—Alab. 10 a 11½—Tenn. 10a 12; N. Car. 10 a 12; Upland 10 a 12—Wmsey, hlds. 1st p. 28½ a —; in bbls. 29½ a 30.—Wool, Washed, Prime or Saxony Fleece 45 a 50; American Full Blood, 38 a 42; three quarters do. 33 a 38; half do. 30 a 33; quarter do. 28 a 30; common 25 a 28. CONTENTS OF THIS NUMBER.

Editorial; On the commencement of the Fifteenth Volume; Stocking Knitting Machine—Letter from T. Speed, giving an Account of the Compass Plant, enclosing some of the Seeds—The Palm Tree—Rock Marl found in Prince Edward County, Va.—Starching—Singular Sagacity of a Pony—Essay on Rotation of Crops, by J. Hamilton Couper, read before the Union Agricultural Society—On Summer Fallows; the objections to them answered; their Use Recommended, by Dan Bradley—Corn Crop Account—Letter from Dr. C. S. Monk, of Baltimore, on the Culture of the Grape; Foreign Varieties Cultivated, Directions for Pruning, Trimming of the Sultana, &c.—On the Culture of Yellow Locust—Eaton's Manual of Botany—Successful Method of Raising Ducks; best Ducks for Breeding; Setting and Hatching; To Destroy Fowl Lice; Duck Coops, Food and Manner of Rearing the Young—Fences—To cure Wounds on Horses and Cattle—Level Roads—Prices Current of Country Produce in the Baltimore Market—Advertisements.

The American Farmer,

Edited by GIDEON B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum: due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect AT THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, MARCH 22, 1833.

The article in the present number, on the subject of dividing large landed estates into small farms and renting them to practical farmers, copied from Sir John Sinclair's Code of Agriculture at the suggestion of a much respected friend, who has devoted much attention to the improvement of our agriculture, is worthy of attention. It will, we know, be said by almost every reader, that the most certain mode of ruining a farm is to rent it to a tenant; and this we also know is true with the system of renting almost universally pursued in this country, where our farming tenantry are, literally speaking, an itinerant community. Under the present system, the object of the proprietor is to get all the rent he can; and that of the tenant, all the produce he can from a single year, without reference by either to the improvement or even keeping up of the estate. The landlord says to himself: How much money can I get for this year's use of my land, and this is all he says. The tenant says: I will make no other improvement of the land than such as I shall reap all the benefit of this year; for I do not know how long I shall remain on it—and this is all he says. Under this system, it will not appear strange that the generality of rented land, in this country, is soon "worn out." But this is not the system recommended by Sir John Sinclair, to which we now call the attention of the reader. Our late worthy friend, Wm. H. Fitzhugh, of Fairfax county, Va. formed a plan of farming, by dividing his large domain into small farms, and renting them, upon very favorable terms, to qualified tenants, for the express purpose of improvement; but we believe the excellent project was defeated by the death of that gentleman. We should be glad to receive the suggestions and opinions of experienced gentlemen on this subject.

The following letter was not intended for publication; but we have concluded that we shall most effectually serve our friend by calling on the practical farmers, who have improved such land, for the information he desires. We have examined our previous volumes of the Farmer, and various other works, and find nothing that exactly suits the case of "W." Our own opinion is, that a course of green manuring and liming would be the best method of improving the land. A crop of cow peas might be ploughed in, followed by a good dressing of lime. If lime be too expensive or inconvenient, the calcareous earths (erroneously called marl) might be substituted. The low wet places should be drained. By a judicious use of green manure and lime, with the assistance of draining, we think "W's" land may be made good. But we hope some of our Virginia friends will take this case into consideration, and favor us with their opinions—as they will be of service to many others, as well as to "W."

King George C. H. Va. }
March 6, 1833. }

MR. SMITH:

As an introduction, I take the liberty of obtruding my standing as a farmer on your notice. I am an inconsiderable brother of that fraternity, owning only a small parcel (five hundred acres) of poor land, which is mostly hilly; that which lies best being level and low, but of a nature the most unfriendly to production, and all improvement. Some parts of the highland have a kindly mixture of aluminous with the silicious earth, so universally pervading the "forest"—or midland of the northern neck; but in consequence, I suppose of the want of the calcareous quality spoken of by Mr. Ruffin, they seem to be in a state of exhaustion. Three barrels of corn on an average, cannot be anticipated with certainty, on my best "shift"—whereof the high ground makes the most

considerable portion. It appears to me that manuring from the farm pen with the stock, which the farm will support, will prove a tedious means of improvement, and upon the whole, I look forward to slender profit, whilst unaided by the discoveries of better endowed neighbors. But it is some hundred of acres or more lying low and much disposed to be wet, that I should be inclined to reclaim, if in my power, from its present state of barrenness. It is called amongst us here, "pewtery," which name is vulgarly applied to land having a tendency to run together after being ploughed, and afterwards grow compact; yielding herbage very moderately and most favorable to wheat, in its best state, but unable to bear repeated cultivation without a barren return. Its physical properties I pretend not to designate in a chemical point of view, though the components appear to the eye to be firm, nearly impalpable sand, and yellow or white heartless clay mingled with it in varied proportions. Land of the same description in the immediate neighborhood bears upon it at this time, tall white oak, gum, &c. These it is in vain to remove, for though bedded, its product, even in the first years, in common herbage or grain, is too small to be considered any thing like a handsome remuneration for the labor bestowed. It washes with the most gentle inclination, taking some time to absorb moisture, but having done so, being mirry in many places.

Now, my kind sir, as you occupy the place of the friend of agricultural improvement, and will not say that I unfairly presume upon your assistance in this my private concern, I modestly, I hope, advance the inquiry for the best course to pursue towards permanent amelioration in this unkindly soil. I am young in this business, and have not had the advantage of the information, contained in the previous volumes of the Farmer, neither know I of the (perhaps) numerous valuable publications on the subject, which might enlighten the darkness with which I am enveloped; nor am I aware that remarks in your paper, of such a nature, tending to elucidate this matter, might possibly be deemed common place, and unneeded by the improved minds of your subscribers generally. If, however, such progress has not been made in the science of agriculture, or if made, you should incline to recur to any remarks, it will be a source of interest and pleasure to your subscriber to see them in any of your subsequent numbers, or any new notices of the kind which may come to hand, or emanate originally from your own pen.

37—We publish the following postscript to a letter just received, for the purpose of shewing what others think of our labors. We wish our friend could convince some of the *hundred thousand farmers* who never read an agricultural paper, of the correctness of his opinion with respect to the American Farmer.

"Inclosed is five dollars for the fifteenth volume of your valuable paper. The last volume has been well stored with the best of information for the agriculturist; in no way could the same knowledge be obtained for the same sum. In my opinion no farmer could lay out the same amount in any other way to the same advantage; he may thereby gain experience, without which he might expend twenty times the amount in one single experiment. With my sincere wishes for its more extensive circulation, &c."

TRANSPLANTING WHEAT.—An account appears in "The Philosophical Transactions," vol. 58, of a gentleman at Cambridge, having divided and transplanted a wheat root several times, and that the result was a produce of 591,000 grains, weighing 47 lb. 7 oz. Mr. Lance, of Lewisham, has this year been experimenting in a similar way. He took up a root in February which consisted of fourteen straws; this was parted into seven roots, and they have since grown to 170 ear bearing straws, besides some small-

er ones. Some of the ears are now (June 16) in bloom, and are six inches long. This is an increase from one removal and partitioning. A rood of ground sown in the autumn with wheat, was thinned out in February, and the thinnings were put into a garden mold that had had a dressing of chalk and sand. These transplanted roots are superior to those in the seed bed, many of them being six feet high, and some ears seven inches long; while the roots have tillered out to forty and fifty straws. They were placed nine inches apart. Transplanted old stubble last year is also in bloom, and are equally as fine as the autumn sown wheat; thus proving what Mr. Lance asserted in his essay "The Golden Farmer," viz. that wheat can be converted from an annual into a perennial plant. A visit to Lewisham would gratify the curious. The process of thinning, dividing, and transplanting wheat would afford excellent employ for redundant laborers in every agricultural district, as well as that of mixing soils, so strenuously advocated by Mr. Lance. Employment would make those happy and comfortable who are now miserably dependant on the poor's rate.

Weekly (Eng.) Dispatch.

BLACK VEILS.—Most persons, when they wish to wash their black crape veils, use vinegar. Washed in coffee, or rubbed with a cloth wet with coffee, gives them a more glossy, black, brighter appearance.—Bombazine dresses are cleaned in the same way. Coffee is better than vinegar, as it has less tendency to decompose the coloring matter.

[New York Farmer.

FOREIGN MARKETS.

LIVERPOOL, Feb. 2, 1833.

We have had but a limited inquiry for cotton this week, but there is no alteration in prices, and the quantity offering is moderate. The sales comprise 100 Sea Island at 12 to 14½d with 10 stained at 7d; 5150 Bowed, 63 to 8½; 2880 Orleans, 63 to 9d; 1140 Alabama, 63-8 to 7-3-8d—making a total, including other descriptions, of 11,830 bales, of which 1000 American are on speculation. Tobacco in good demand; about 220 hds. Virginia stemmed taken by trade and speculators. No transactions in Carolina rice, except for a parcel damaged. 200 brls. Montreal pots disposed of at 25s 6d. A good inquiry for N. York sowing flaxseed; sales amount to 1000 hds. one-half at 81s, price of remainder not known. No transactions in cloverseed or quercitron bark. Turpentine lower; 15000 brls. sold at 11s 6d; a parcel offered at auction withdrawn—the same as to American tar, which is held at 11s 6d.

LIVERPOOL COTTON MARKET, Feb. 4.

Although the demand has been unusually limited, there is not the slightest alteration to report in the prices of any description; the quantity on show throughout the week has not been more than sufficient for the wants of the buyers, and on Friday there was evidently less disposition on the part of the holders to meet the demand, without, however, producing any sensible effect upon prices. About 1000 bales of American have been taken on speculation this week, and 2100 bales American and 300 bags Brazils have been forwarded into the country, unsold, in the course of the last month. The sales amount to 11,830 bales, as follows:—100 Sea Island at 12d to 14½d; 10 stained, 7d; 5150 Bowed Georgia, 63d to 8d; 1150 Mobile and Alabama, 63 to 7-3-8d; 2880 New Orleans, 63 to 9d; 610 Pernambuco and Ceara, 8-3-8d to 9d; 350 Bahia and Macello, 74 to 8½d; 100 Maranh, 84 to 9½d; 250 Egyptian, 84 to 9½d; 680 Carthage, 6d to 6½d; 30 Syria, 7d. The imports are 18,101 bags.

AGRICULTURE.

(From Sir J. Smollet's Code of Agriculture.)

TENURE.

WHETHER IN PROPERTY OR ON LEASE.

In this section it is proposed to examine the advantages and disadvantages attending the occupation of land, either by the proprietor himself, or by tenants holding under him.

1. PROPRIETORS OCCUPYING THEIR OWN LAND.

It is certainly in various respects attended with public advantage, that a large proportion of the soil, should be the property of one class of the community, and in the occupation of another. In some of the American states, where, from a scarcity of population, leasehold tenure is hardly known, the land is often so much exhausted by the inattention of the owners, who think they may take any liberty with their own property, that in many districts the crops of wheat, do not exceed an average of seven or eight bushels per acre. How different is the case in this country, where the owner, instead of cultivating his own fields, lets them to another. A careful landlord, indeed, considers himself as a trustee for his family, and for the public. He will not suffer his fields to be exhausted, by improper management, or injudicious rotations; and when he grants a lease to a tenant, it is either to a person in whom he can safely place confidence, or under such covenants, as are the most likely to prevent that great source of public wealth, the soil of the country, from being injured by improvident management. It must be admitted, however, that such covenants are often very injudiciously drawn up.

When a tenant also, has a rent to pay to a landlord, it has a strong tendency to render him industrious. Without that spur to exertion, he would not take half the pains he usually does, to cultivate his farm, or to supply it with stock. The burden of rent is likewise attended with another advantage, for in order to be enabled to pay it, the farmer finds it necessary to supply the markets more regularly. When persons have no such stimulus, they are induced to keep up their produce, that they may enhance its value.

Besides, a tenant who cultivates the soil as a profession, has but one object in view; and he is therefore more likely to manage the concern better than a proprietor, who has often other avocations to distract his attention. Not only is the tenant necessarily more attentive to his business, but he carries it on at less expense: his cattle and servants do more work; the produce of his farm is more carefully looked after; and no money is expended, without the prospect of an adequate return. Expensive improvements, such as erecting commodious buildings, making roads, enclosing, draining, irrigating, and perhaps a very great application of calcareous matters, may be advantageously executed by the landlord; but in regard to raising the products of the soil, by judicious rotations of crops, complete aration, abundant manuring, selection of the best seeds, &c. an intelligent farmer has evidently an advantage.

As a proof of the justness of these doctrines, it is a well known fact, that small proprietors, when they are men of sense and ability, frequently let, or sell their own estates, and take the lands of others on lease; knowing well, that if they resided on their own property, they would be tempted to live like gentlemen, and to indulge in idleness and inactivity.

* General Report of Scotland, vol. i. p. 176.

† The Rev. Dr. Cartwright recollects a curious circumstance of a person who resided, about fifty years ago, in a village on the road between Newark upon Trent and Stamford, who had been obliged to sell his estate, took it on lease, and made as a farmer, so much money, that he was able to re-purchase it. Small proprietors in general are seldom possessed of capital sufficient to improve their lands, and frequently indulge

instances as have not been wanting, where, owing to negligence, or want of capital to improve it, the owner of an estate, has been obliged to sell it, and has hired the same land to farm, at a fair rent, and has done well.*

When the proprietors of considerable estates, cultivate their own land, they may have one of five objects in view: 1. Accommodation; 2. The pleasure of farming; 3. Profit; 4. To make useful experiments; and, 5. The general improvement of their property.

1. It is not only a healthy, but a most useful employment, for gentlemen residing in the country, to have some land in their own possession, for the purpose of providing themselves with various articles which their families may require. Perhaps these articles might often be purchased fully as cheap at market; and it might be more profitable to the proprietor, to let the land at a fair rent, than to occupy it himself; but the occupation of land is a source of rational amusement, and it is desirable for every proprietor residing in the country, to have a spot he can call his own, where he and family can take air and exercise. Besides, if attention to a large extent of arable land be found inconvenient, so much corn need only be raised by a landholder, as may be necessary for his own purposes, and after his fields are enclosed, and laid down to grass, he may let them to farmers or graziers, the proprietor reserving what is absolutely necessary for his own accommodation.† What the extent of such accommodation land should be, need not be here discussed; as it depends, upon the establishment kept up by the proprietor, the portion of time spent by him in the country, and the degree of superintendence that he can give to his farm.

2. When operations of agriculture were first attempted, it was for the purpose of procuring the *mere necessities of life*, but when these were once obtained, its conveniences and comforts were next sought after, and ultimately its refinements. Hence agriculture, which originally was considered to be a rude and simple source of employment, became, in process of time, a *liberal art*, capable of contributing to improve the scenery of a rich domain, or to shelter and adorn the residence of the great and powerful.‡ Hence *ornamental agriculture* arose, as distinguished from the useful. The distinction between them is, in general, abundantly obvious. The scheme of culture which a gentleman may pursue in his park, or on lands near his seat of residence, is generally a very different one from that a husbandman should adopt in his fields. The principle of the former is taste, that of the latter, economy, or thrifty management; the characteristic of the former, is *ornament*, that of the latter, *utility*; and the object of the former, is *pleasure*, that of the latter, *profit*. When the latter object is pursued on an extensive scale, it becomes a serious employment, requiring constant and great attention.

3. Though there are instances of spirit and great application, producing effects creditable to the owners of estates, who cultivate their own lands, for arable crops, yet their profit, generally speaking, is much less than if the same land were occupied by a farmer. Proprietors rarely attend to all those minutiae which a corn farmer must not neglect. Neither do they regularly oversee their servants, examine the state of

notions, which disqualify them from the pursuits of industry. *Cumbrian Misc. Report*, p. 20.—Hence, in the progress of society, this class of men gradually disappear. *Stirlingshire Report*, p. 69.—It is found more profitable, to have a capital in money, judiciously employed in farming, than a capital in land.

* Staffordshire Report, p. 39; Ayrshire Report, p. 77.

† General Report of Scotland, vol. i. p. 172; Husbandry of Scotland, vol. ii. p. 139.

‡ Cicero, in his Cato Major, has well observed, "That there cannot be a richer, or a more ornamental object, than a well cultivated field. *Agro bene culte, nil potest esse, nec usu uberius, nec specie ornatus.*"

their working cattle, attend fairs and markets, nor personally superintend the progress of all their farming operations. These duties, therefore, are commonly entrusted to a bailiff, [overseer,] who is seldom sufficiently qualified for them all; nor does he almost ever possess so much attention and frugality, as a prudent and well-informed farmer, whose personal interest is at stake, and who manages all his transactions. Though a landed proprietor, therefore, may have acquired sufficient practical knowledge of husbandry, to superintend the management of a farm; yet his other pursuits preclude him from paying such attention to those inferior objects, without which, it is impossible that he should farm to advantage, upon a great scale. Hence a species of farming arises, which is justly denominated *profuse agriculture*, founded on unlimited expense in tillage and manuring; by which, perhaps, double crops are obtained, but are raised at triple cost. Thus, with delusive notions of profit, many are betrayed into real, though unheeded loss. Indeed it is well known, that gentlemen cultivators, after having pursued the profession of husbandry for some years, with much ardor, have frequently relinquished it with chagrin. Where their farming, however, is carried on with economy, and in moderation, it is of much use, keeping up a spirit of experiment in cultivation, and in particular, tending to promote the improvement in stock.

4. It is next proper to observe, that since the attention of the public has been so much directed to agricultural pursuits, many respectable proprietors of land,* have cultivated extensive tracts of country, with the view of trying useful experiments, and disseminating a knowledge of agriculture in their respective neighborhoods. Nothing can be more laudable than such pursuits. The spirit of improvement which they have thus excited, and the important facts which they have established, must be in the highest degree gratifying to themselves, and useful to their country.†

5. Some landlords in remote and unimproved districts, convinced that example, and not precept, will alone dispel ignorance, and remove prejudices in rural arts and practices, have resolved to take a farm into their own hands, with a view of showing an example of correct husbandry to their tenantry; and they

* Among these, the Duke of Bedford, the Earl of Egremont, Lord Somerville, Sir Joseph Banks, Mr. Coke in Norfolk, Mr. Western in Essex, Mr. Curwen in Cumberland, Sir W. W. Wynne, and Sir Robert W. Vaughan in Wales, and others might be enumerated.

This has likewise been much the case in Ireland, where of late years, the landed proprietors have become agriculturists, either through necessity, (not having been able to dispose of their lands to advantage,) or from having caught the patriotic spirit of improvement, so laudably set by the sister kingdom. This has been attended with many beneficial consequences to that country. Gentlemen, instead of devoting their time only to pleasure and amusement, as was formerly the case, are now proud of being considered zealous improvers on their own estates, and do not consider a knowledge of rural affairs derogatory to their condition in life.—*Remark by Edward Burroughs, Esq.*

† Husbandry of Scotland, vol. ii. p. 140. Formerly a nobleman who directed his attention to experiments in cultivating the various and useful tribes of the vegetable kingdom, was considered by his brother peers as degrading his high station in life. But now, what a change! Every where proprietors are to be met with, who, by every means in their power, either by precept,—by example of improved culture,—by publications,—or by premiums, combat the prejudices of their uninformed tenantry, and become a blessing to their neighborhood.—*South Wales Report*, vol. i. p. 178.—In Ireland also, many of the nobility and gentry have become intelligent farmers; but as they seldom attend to the practical part of it, they often find it difficult to prevail upon their stewards to follow any new system. It frequently happens, that a failure in this case, either through ignorance or obstinacy, prevents a repetition of the intended improvement.—*Remark by Edward Burroughs, Esq.*

look for profit, not from the produce of the farm they occupy, but from the general improvement of their estate.* In other cases, improvements have been carried on by the proprietors on a still greater scale. When their estates have been in bad order, the farms ill arranged in regard to extent, figure, and boundaries, and the farmers dispirited, poor, and unskilled in agriculture, they have taken a considerable tract of country into their own hands, and, after improving it, have let it to enterprising and skillful farmers. They have then removed their servants, cattle, and implements of husbandry, to another part of the estate, and after treating this in the same manner, they have proceeded to others, as far as circumstances rendered it expedient.†

It is well known, however, that proprietors have in general derived the greatest profit from farms, which they have only partially improved. Indeed it seldom happens, that a landed proprietor can thoroughly improve a farm, without incurring much unnecessary expense; whereas, when a foundation has once been laid, a judicious farmer, with more attention and economy, can accomplish the same, or nearly as much improvement, on far more moderate terms. Nor, in economical agriculture, is any practice worthy of attention, in which the expense incurred, will not be repaid with a fair profit.

2. FARMERS OCCUPYING LAND.

In former times, the connection between a landlord and his tenants, was of a military description. The proprietor of an estate was himself a warrior; and those who possessed land under him, were his soldiers, who were bound to military service, and who paid him hardly any rent in money, but only some personal services, and a moderate quantity of some articles in kind, for the maintenance of his family.

When the feudal system was abolished, the landlord, at first, still considered himself as the patron of those who were placed under him. The rents continued low, the occupiers of the estate claimed, from generation to generation, under the name of "Kindly Tenants," a sort of tacit patrimonial interest in their respective possessions; and as they paid very inadequate rents, and had no permanent security in their possessions, nothing could exceed their indolence, their ignorance, and of course the poverty of their condition.

The connection between the two classes, is now of a description totally different. The landlord considers himself as the owner of an estate, of which he must make the most he can, for the benefit of himself and family. He lets it for a certain number of years, to persons possessed of skill, integrity, industry, and capital, under the obligation of paying him annually, a specific share of the produce, converted into money, besides being bound, if not to improve the value of the property, at least that it shall not be deteriorated during the currency of the lease. The contract becomes of course more of a mercenary nature, without, however, totally destroying ties of a more pleasing nature; for the landlord, on the one hand, must feel himself deeply interested in the success of his tenant, on which his own income and prosperity materially depend; while the tenant on the other, looks up to his landlord as a friend, whose interests are necessarily interwoven with his own, and

who will naturally be inclined, to give an industrious and improving tenant a preference, when the farm is to be re-let.

Under this system, it is essential both for the landlord and tenant, that the connection between them should be established on just and liberal principles, so as to induce men of knowledge, enterprise, and capital, to devote their attention to the art of husbandry. That can only be expected, where leases are granted. These furnish the most beneficial species of encouragement to agricultural improvement; indeed if any great exertions are necessary, they are not to be attempted without that security. Where a proprietor, therefore, does not incline to occupy his land himself, he naturally resolves to surrender the temporary possession of it to others, under such conditions as may be mutually advantageous.

A lease, indeed, is properly a contract, founded on the principles of equity, between two men for their mutual advantage. The one possesses an absolute right in the property of a certain tract of land and its produce, the other purchases the temporary privilege of appropriating the produce of that land to himself, at a certain stipulated price. The proprietor of an estate, may thus be considered as in the possession of a certain fixed capital in land, which is capable of producing, when duly cultivated, a certain annual value. The cultivator of the soil, on the other hand, possesses a moveable capital, consisting of the necessary funds for stocking a farm, his knowledge in the art of agriculture, and his industry. Thus situated, the parties, like other men who wish to enter into a joint concern, are induced, by the prospect of mutual advantage, to agree to unite their capitals, for the purpose of assisting nature in producing human subsistence; and their respective interests, having been mutually considered, their agreement constitutes the terms, or specific articles of the lease. On this plain principle depends the connection between landlord and tenant. The capital invested by the cultivator, the rent he pays, his skill and labor, the contingencies, and chance of loss that may arise, from the inclemency of the seasons, must all be compensated by the value of the produce of the soil. Where these principles are fully understood and acted upon, both proprietor and tenant will be placed in the most favorable situation, of which the nature of the transaction admits. But where these are departed from, the interest of the one, or of the other, or perhaps of both, must suffer, in proportion to the degree of aberration from that equitable line, which so distinctly marks their respective rights and obligations.

In regard to the manner of settling a lease;—the period of entry, and the regulations therewith connected;—the duration of leases;—and the covenants to be inserted in them, as these particulars require more detail than is consistent with the nature of a work restricted to general principles, it is proposed to discuss them in a separate paper. As to the form of a lease, and the stipulations essential for the interests of the two parties, these must vary so much, that it is hardly possible to reduce them to one uniform plan.

RENT.

The price periodically paid by the occupier, to the owner, for the use of his land, is called *rent*. It formerly consisted of a great number of particulars; as personal services, trifling sums in money, and various articles in kind, as grain, hams, pigs, poultry, &c. In countries unprovided with a sufficient quantity of circulating medium, payments in kind were unavoidable; nothing, however, could be more injudicious, when circulation became more abundant, than such payments. The grain, and other articles of a similar nature, were uniformly of inferior quality, and the exaction of personal services, was of little advantage to the landlord, while it was an oppressive burden on the tenant, obliging him to keep a greater number of men and horses than his own farm requir-

ed, and often interrupting the most important farming operations. Rent, therefore, in the present more advanced period of society, ought in general to be restricted to money payments; and the imposing of any burden ought to be avoided, which has a tendency to impede the industry of the tenant, or to withdraw his attention from the management of the farm.

The amount of rent, in a general point of view, must always depend on a variety of circumstances; as the wealth of the country;—the state of its circulation;—its population;—the price of produce;—the amount of public and other burdens;—the distance from markets;—the means of conveyance;—the competition among farmers;—and other less important considerations;—but the rent of any particular farm must be regulated by,—the nature of the soil;—the duration of the tenure, and the covenants contained in the lease;—the capital to be invested by the farmer in its culture;—and the expenses to which he is liable.

Poor land cannot possibly pay the same proportion of rent, according to the amount of its produce, as the rich and fertile. The labor of ploughing, harrowing, sowing, &c. when the land is in cultivation, is nearly the same, and yet the produce is greatly inferior, not only in quantity, but in quality. Indeed, where the produce is inconsiderable, or the quality much inferior, the whole, or nearly the whole, may be swallowed up by the expense of labor, and no rent whatever can be afforded, more especially in adverse seasons.

The duration of the tenure must have a considerable effect, in fixing the rent. No farmer can afford to pay the same sum for land on a short, as if he held it on a long lease. The covenants, also, which are in fact a species of rent, must influence the money payments.

Rent must also depend on the capital invested in the cultivation of the farm. Thus, if a farmer can lay out only 4*l.* of capital per acre, he may not be able to afford for it a higher rent than 10*s.* per acre; if he lays out 7*l.* he may pay 14*s.*; and with a capital of 10*l.* per acre, he may be enabled to pay 18*s.* or 20*s.* of rent. Hence the advantage of wealthy tenants; and hence the justice of the maxim, "That capital in the hands of the tenantry, is of as much consequence as the quantity of the land."

It is obvious, that all the expenses of a farm, must of necessity be defrayed by a sale of the produce, before any provision can be made for rent, and when these charges absorb more than the whole produce, there is nothing left for the payment of the landlord. The increase of the tenant's expenses, taxes, assessments, tithes, law charges, and stamps, as well as losses by bad debts, and otherwise, would have extinguished rent several years ago, if the price of the bushel of corn, and the pound of meat, had not advanced in proportion to the tenant's expenses, and the other burdens to which he is liable. In the present circumstances of the country, high prices for corn and meat, are indispensably necessary to the existence of rent, more especially upon inferior soils.

Upon the subject of rent, it is proposed to consider: 1. What proportion of the produce should be paid to the landlord; 2. Whether a specific sum in money ought to be paid, or whether it should vary according to the price of produce; and, 3. At what periods the rent should be made payable.

1. *Proportion of Produce as Rent.*—This is a question, that has long been considered as abstruse, mysterious, and very difficult to resolve. Some have supposed, that one-fifth was a reasonable proportion, while others contend for a fourth, or even a third

*Annals of Agriculture, vol. xxiii. p. 335. Mr. Young here justly questions the good sense and understanding of these landlords, who argue against rich tenants;—who are jealous of seeing a farmer on a good horse;—and think it presumption in him to drink a bottle of wine. In other words, that is saying, that it is better to receive only 12*s.* than 20*s.* of rent per acre.

*Some are of opinion, that instead of this kind of experimental farming, it would be of more advantage, both to the proprietor and to the district, to encourage a farmer from another county to set the example, as farmers are, in general, more ready to imitate the practice of their equals, than that of a large proprietor, who is so far removed from their own station in society, and, as they observe, who pays no rent for his land.—*General Report of Scotland*, vol. i. p. 172.

†In Scotland, this plan has been frequently adopted, and with much success. The exertions of an Earl of Findlater, of a Count of Argyll, and of a Robert Barclay of Cry, of a Henry Home Lord Kames, stand eminently conspicuous in that honorable list.

part of the produce of arable land.* But all former calculations on this subject, are rendered fallacious, by the effects of modern improvements. The rent ought certainly to depend upon the amount of the *disposable produce*; and that produce in grain, is greatly augmented, both by a diminution of the consumption on the farm, effected by improved implements, and a more correct arrangement of labor, and likewise a better cultivation of the land in tillage. Hence, while the price of wheat has greatly advanced during the last twenty years, above the average price of the preceding twenty, the rent of land has not only risen, but in a higher proportion. More grain, and that of a better quality, has been produced on the same extent of land, and a greater amount of disposable surplus has gone to market †

Out of this surplus disposable produce, it is evident, that the rent must be paid. But it is difficult to divide its amount between the landlord and tenant, as so much depends upon the seasons, and on the prices of the different articles which the farm produces. In bad seasons also, every deficiency of produce, in the acres set apart for supporting home population, must be made up from the disposable surplus; nor is it possible to apply the same rules to all situations, soils, and climates, in all the various districts of an extensive country. It may be proper, however, to give some general idea, of the proportion of produce paid as rent, 1. In Scotland; and, 2. In England.

1. In Scotland, the following table states what is considered to be a fair proportion, where the land is cultivated.

TABLE OF RENT ON ARABLE FARMS.

	Per English Acre.
1. Where land produces 10l. 10s. per acre, per annum, one-third, or	£3 10 0
2. Where land produces 6l. 12s. per annum, one-fourth, or	1 13 0
3. Where land produces only 4l. 5s. per acre, one fifth, or	17 0s

In regard to grazing farms, they are let on principles totally different from the arable, namely, according to the quantity of stock they can maintain; and as they are not liable to the same expense of management; both the landlord and the tenant receive larger shares of the produce, than in the case of arable farms.

2. In England, on the other hand, the husbandmen and their landlords, are in a kind of partnership, in which the tenant provides all the capital, and undertakes the management of the whole concern; as a remuneration for which, and for the interest of the money he has invested in it, he is allowed on arable land, equal to what is considered to be one moiety of the surplus, after defraying the expenses of cultivation, the taxes to which he is liable for the farm he occupies, and every other on-going. Hay land requires much less of his attention, and for this he only obtains one-third of the surplus. But the profits of grazing, depending much on superior judgment in

buying and selling stock, as well as skill in preventing, or curing their diseases, the grazier is entitled to a share of the surplus, fully equal to that of his landlord.

It has been contended, as a *general principle*, that as both the expense of cultivating land, and the value of its produce, are infinitely various, a farmer ought to calculate, what profit he can make on his *whole farm*, without entering into details; it being of little consequence to him, whether he pays at the rate of 10l. or 10s. per acre, provided he makes an adequate interest on the capital invested. That is certainly a fair criterion on which a tenant may calculate what he ought to offer; but a landlord, in estimating the rent he ought to insist on, must take into his consideration, the produce that his land is capable of yielding, and what proportion of it, or of its value, at a fair average, he has reason to expect, under all the circumstances of the case, which ought not entirely to depend, on the exertions of a timid, or penurious tenant.

What are the profits to which a farmer is entitled, is a subject of much dispute. On the one hand it is contended, that the produce of land, is of such universal and absolute necessity to the existence of mankind, that it is not reasonable it should yield to him who raises it, more than a fair profit. On the other hand it is urged, that a farmer is entitled to be fully recompensed for the application of a considerable capital, exposed to the uncertainty of the seasons, when it is managed with economy, and conducted with industry and skill; and it has also been observed, that it is seldom more money is got by farming, than an adequate interest for the capital invested. This is owing to *competition*, the articles produced, being in numberless hands, who must bring them to market; and *necessity*, the goods of the farmer, being in general of a perishable nature, on the sale of which he depends, for the payments he has to make, and the subsistence of his family.

To prove how moderate the profits of farming in general are, it appears from the most careful inquiries, that on *arable farms* they rarely exceed from ten to fifteen per cent. on the capital invested, which is little enough, considering that few employments are more subject to casualties than farming, or require more uniform attention. Some arable farmers, possessed of superior skill and energy, and who have got leases on reasonable terms, may clear from fifteen to twenty per cent. while others, who are deficient in these qualities, or pay too high rents frequently become insolvent.

In grazing farms the case is different, as they are attended with less expense of labor, and produce articles of a more luxurious description, for which a higher price will be given. Hence in such farms, fifteen per cent. and upwards, is not unusual. Besides, the grazier is more of a merchant than the mere arable farmer; is frequently buying as well as selling stock, and sometimes makes money by judicious speculations, though occasionally, from a sudden fall of stock, his losses are considerable. The grazier who breeds superior stock, and thence incurs great expense, is certainly well entitled, to more than common profit, for his skill and attention.

It has been observed, however, that a farmer seldom makes much money, unless he is most advantageously situated in the neighborhood of a great town, or unites with farming, some other profitable employment. But those who have capital and ability, adequate to the management of more than one concern, merit to be amply rewarded for their superior skill and industry.

2. *Mode of paying Rents.*—In regard to the mode in which rent should be paid, it is proper to consider, whether the whole, or, at least, part of the rent, ought not to depend upon the price of grain, not for the season, but on an average of a certain number of years preceding that for which the rent is due. By this plan, neither the landlord, nor the tenant, can

suffer from the fluctuating price of grain; whereas, without some such arrangement, the tenant on the one hand cannot make a fair offer of rent, lest the price of grain should fall too low; nor, on the other hand, can the landlord grant a lease of considerable duration, lest the price of grain should, in the progress of time, rise much higher. It seems therefore to be for the interest of both parties, that, on arable farms, a part of the rent should be payable in money, and part in corn, not in kind, but in money, according to the average value of a number of years. This plan is enforced by law, to the extent of one-third, in college leases; and thus an income is secured, in some degree proportioned to the value of money.

This mode, however, is not without its difficulties. The amount of rent, for improvable, and well-cultivated farms, does not depend so much on the price of grain, as is commonly imagined. A large proportion of such farms, usually produce green crops, the value of which depends upon the prices of beef, mutton, and wool, and not on that of grain. Various circumstances also may arise, which may reduce the price of particular sorts of grain below its usual level, (for example, barley, when the distilleries are stopped;) or may raise it disproportionately much higher, in case a large proportion of the wheat crop should be destroyed by rust or mildew. But if the proposed payment, by the conversion of corn into money, be extended to the various sorts of grain usually cultivated in the district, and be restricted to *one half of the rent*, it does not seem liable to any material difficulty. If the payment also, depends, on the average of seven or more years, the main objection to a coin rent, that the farmer is often liable to pay the most, when he is the least able to do it, is removed.

3. *Periods of Payment.*—These ought to be made so convenient to the tenant, that he may not be under the necessity of selling the produce of his farm to disadvantage, for the sake of ready money; nor should he be compelled to pay his rent out of his capital, for that would cripple all his future exertions. The periods should vary according to the nature of the occupation, and the time when the tenancy commenced. It is advisable, however, to have the rent payable at two periods of the year, in order to divide the burden of the payment, and that the tenant may not have any money unemployed, which too often leads to waste, and unnecessary expenses.

On the whole, the most successful farmers are those, who embark a capital sufficiently large in their undertaking;—who feel it their duty to watch over that capital with unceasing care, and to add to it whenever it is practicable;—and who have agreed to pay a fair, but not a speculative rent, for the lands they cultivate.

(From the Southern Agriculturist.)

ESSAY ON ROTATION OF CROPS;

By J. HAMILTON COOPER;

Read before the Union Agricultural Society.

(Concluded from page 3.)

In the preceding observations, an attempt has been made to sketch out, and to elucidate by the sound theories of science, those leading principles of a rotation of crops, which have received the sanction of the ablest practical and scientific agriculturists. Before proceeding to illustrate them by the practices of the best cultivated countries, it may not be useless to present, in a more distinct form, the following recapitulation.

First principle.—In the selection of crops, to consult the climate, soil, situation, the den and resulting from markets, and the other circumstances which constitute the peculiarities of local position.

Second principle.—Plants possessing a system of broad leaves, are to be alternated with those having narrow leaves.

Third principle.—Fibrous rooted are to be alternated with tap and tuberous rooted vegetables.

* It is an old remark, that every arable farm ought to produce three rents; one for the landlord, one for the expense of management, and one for the farmer; to which a fourth ought now to be added, for taxes, and parochial assessments.

† The use of two-horse ploughs, and the invention of the thrashing-mill, by augmenting the disposable produce, have greatly augmented the rents in Scotland.

‡ Husbandry of Scotland, vol. ii. Appendix, p. 173. In Chapter V. shall be given, very important estimates of the amount of disposable surplus, on a clay land, and a turnip-soled farm.

§ Dr. Coventry has drawn up "Estimates of the Produce and Rent of Arable Lands," varying according to the fertility of the soil, and on the climate or height of situation; with some explanatory observations, which are well entitled to the attention of proprietors, and their stewards, on the one hand, and the occupiers of the soil on the other.

Fourth principle.—The recurrence of the same plant, on the same field, or of plants of the same character, is to be removed as far as possible. And their return should be so much the longer delayed, as they have the longer occupied the soil.

Fifth principle.—Plants which during their growth require the operations of stirring the earth and weeding, to be alternated with those which do not.

Sixth principle.—The application of manure to be made to the most valuable and exhausting crops, as far as may be consistent with the preceding principle.

Seventh principle.—The succession of crops should be so arranged; that the work which they require shall follow in easy, regular, and economical order.

Eighth principle.—Land should be left bare as short a time as possible, and should be kept covered with plants valuable in themselves, or which contribute to the increased value of those which are to follow.

The first example of a course of crops will be drawn from French Flanders, a part of Europe inferior to no other in the value of its crops, the garden-like culture of its fields, and the skill with which its diversified products are combined, which claims to be the "true cradle of regular and systematic rotations of crops;" in which they have been pursued for a century; and when the fertility and beauty of the country—a happy and comfortable population amounting to nearly an individual to two acres of land, and a disposable surplus of one third of the products of the soil, attest the perfection of their peculiar system of agriculture, and is the highest eulogium which can be paid to the value of a rotation of crops.

In this district the courses of crops vary with the soil to which they are to be applied, not only in the kind but in the number of the plants of which they are composed: presenting a nice adaptation of the character of the vegetable to the peculiarity of the soil; and fulfilling all, or nearly all of the conditions of an enlightened system of rotations. Amidst the diversity which exists, from this cause, a leading principle is still observable in all of the courses whether of long or of short duration. The plants which compose them are thrown into three great divisions, comprising different natural families.† These divisions are made to alternate with great regularity, although the plants contained in them are frequently deranged in the order of their succession, to meet the fluctuations of markets, and the vicissitudes of the seasons.

The first division contains *Oleaginous* plants, as rape, flax, poppy, cameline and hemp; and plants of the *Solanææ* family, as potatoes and tobacco.

The second, embraces *Cereal or grain* plants, as wheat, barley, oats and rye.

The third, *Leguminous* plants, as beans, peas, vetches, lentils, clover, sainfoin and lucerne.

This mode of succession will be best illustrated by the following example taken from the vicinity of Lille.‡ It is a rotation on a farm of forty-eight acres.

1st year.—Plants of the 1st division.—Rape, with stable and liquid manure, 4 acres, followed as a 2d crop, by 2 acres of carrots, beets or turnips.

2d year.—Plants of the 2d division.—4 acres of wheat not manured; 2d crop, 2 acres of turnips, carrots, or cabbages, with liquid manure.

3d year.—Plants of the 3d division.—4 acres of beans.

4th year.—Plants of the 1st division.—4 acres of potatoes, with stable and liquid manure.

5th year.—Plants of the 2d division.—2 acres of barley, with clover cut the first year. 2 acres of oats, do. do.

6th year.—Plants of the 3d division.—4 acres of clover, three cuttings.

7th year.—Plants of the 1st division.—3 acres of flax, with liquid manure and oil cakes. 1 acre of tobacco, same manure, followed as a 2d crop, by 2 acres of turnips, carrots, &c.

8th year.—Plants of the 2d division.—2 acres of bearded wheat, 2 acres of rye, followed by carrots, turnips, &c as in 2d crop, with liquid manure.

9th year.—Plants of the 3d division.—2 acres of winter barley, cut green, 2 acres winter forage, followed by 2 acres of cabbages, beets, or turnips, as a 2d crop, with liquid manure.

10th year.—Plants of the 1st division.—Rape, 4 acres, for the seed, with stable and liquid manure, followed as a 2d crop, by 2 acres of turnips, carrots, &c.

11th year.—Plants of the 2d division.—4 acres, wheat, followed by 2 acres turnips and carrots, as a 2d crop.

12th year.—Plants of the 3d division.—3 acres beans, 1 acre winter barley, cut green, followed by a nursery of rape plants as a 2d crop, with liquid manure.

In this course of crops there are four returns of the three great divisions. Each return fulfils most of the important principles. *The first year*, the land is well manured, and well stirred and weeded. The application of manure is made to the most exhausting and valuable crop of the series. At the end of this year, the soil is left rich, well stirred and clean; qualities which are required by the grain crops which are to follow. The crops of this year are removed in time, to admit of the preparatory operations for those of the next. *The second year* the land is occupied by grain crops, which succeed perfectly well, as it is clean, enriched and well stirred. No manure is added this year, as its recent application fills the soil with weeds, and from an excess of vegetation, occasions the lodging of the grain. *The third year*, it becomes necessary to replace the grain crops, which have left the soil impoverished, hard, and foul with weeds, by some crop which is ameliorating and cleansing. Hence, the cultivation of leguminous crops this year, which by their broad leaves and succulent stems, draw their nourishment from the atmosphere, and by the decay of their leaves, stems and roots convey it to the soil: which by their system of tap-roots pulverize the earth; and by their dense shade, and the culture which they require, destroy the weeds produced by the preceding crop.

These effects are reproduced whatever may be the length of the rotation. "It may be seen," says the author from whom this example is taken, "that in this rotation of twelve changes, each variety of oleaginous, cereal and leguminous plants only returns twice; that the greater part and the most exhausting, as potatoes, flax, are only cultivated once. The great condition, therefore, of an extreme variety of crops is accomplished, and all the others are exactly fulfilled, since ameliorating crops and hoed and manured plants precede and follow the grain crops, which have the double inconvenience of exhausting and infesting the earth with noxious weeds."

The productiveness of this rotation is shown by its yielding four grain, four oleaginous, four leguminous, and four secondary root crops; being sixteen crops in twelve years.

The frequent introduction of double or secondary crops, forms a striking and valuable feature in this and all the other rotations of Flanders. One not less valuable is, that fallows, whether naked or covered, form no part of them.

It would be interesting to enter into an examination of the course of crops adopted in Dutch Flanders, as they present many useful hints, and valuable lessons, but I fear that I have already exhausted the

patience of the society; and as I purpose, should leisure permit, to offer at some future time, the result of a personal examination of the agriculture of that country, I pass from it with the less reluctance to the rotations of England.

These are much less perfect than those of Flanders, as they include, on strong clay lands, a naked fallow, (a practice justly exploded by the best agriculturists,) and from the climate and peculiar circumstances of the country, admit a less variety of plants, and consequently of a less protracted course of crops. These limited rotations are, however, managed with much judgment. I will instance only two.

The first is the celebrated Norfolk rotation; adapted to a sandy loam. The change which it has produced in the agricultural character of the country is so notorious, as to be familiar to all. An examination of the high state of culture, and of the beautiful crops produced by it, on soils of the most unpromising appearance, enable me to bear personal testimony of its excellence.

1st year.—Turnips, on 27 inch ridges, with from 8 to 15 tons of manure, and one-fourth of a ton of oil cake to the acre. Preceded by four ploughings and harrowings, and cultivated by two or three horse and hand hoeings. The crop cut on the ground by sheep.

2d year.—Barley, sown in drills of 7 inches, with-out manure. Ten pounds of white clover and 16 quarts of rye grass seed sown with it.

3d year.—Clover and rye grass.

4th year.—Wheat, in drills 9 inches apart.

This course is sometimes prolonged to five years, by continuing the clover and grass a second year.

Its excellencies are, that turnips and clover which are ameliorating crops, are alternated with barley and wheat, which are exhausting; plants with different systems of roots succeeded each other; the same plants recur only once; the manure is applied to the preparatory and cleansing crop of turnips, which being an ameliorating one, and eat on the ground by sheep, leaves the soil in a high state of neatness and fertility, to receive the exhausting crop of barley which follows; the interval between the wheat and turnip crops admits of the production of the fine tilth which the latter requires; the clover and grass induce the closeness of staple, desirable on a sandy soil for wheat, while the treading of the land by sheep, corrects that openness which is one of the defects of light, gravelly lands. The faults in this course are, that there is a waste of manure in feeding turnips on the ground, and that the shortness of its duration does not admit of the deficiency of manure which results from this cause, and from the number of exhausting crops, being supplied from additional ameliorating crops. These defects have led Mr. Coke to combine it with a second rotation, in which a peas crop succeeds a second year of grass, making a six years course of, 1st, turnips; 2d, barley; 3d, cocks-foot and other grasses pastured; 4th, grass pastured; 5th, peas; 6th, wheat. In this rotation the increase number of ameliorating crops, corrects the defect of the preceding.

The next examples which I shall offer to your consideration are taken from Italy, a country which approaching our own in climate and vegetable productions, becomes the more interesting to us for modified imitation.

On the rich alluvial plains of Po, in the vicinity of Parma, the following course of crops is that generally pursued.*

1st year.—Indian corn and hemp, manured.

2d year.—Wheat.

3d year.—Winter beans.

4th year.—Wheat, manured.

5th year.—Clover, turned in after the first cutting.

6th year.—Wheat.

This is an instance of highly productive, and very exhausting rotation; but which is sustained by the

* Yvart.

† Cordier. Memoire sur l'Agric. de la Flandre Française.

‡ Idem. p. 291.

♦ A mixed forage crop, principally of legumes.

• Lettres Ecrites d'Italie à M. Pietet.

great natural fertility of the soil, maintained by the abundance of manure which is afforded by an irrigated meadow of more than a fourth of the extent of the arable land, cut three times a year, and consumed by large stocks of cattle.

On the rice lands of Lombardy, the rotation adopted is of five years, being three years in rice, and two in natural meadow. For three years the land is planted in rice. "No manure is applied during this time; the continuance of the water would neutralize the effect, and its presence is sufficient for the vegetation. But after these three consecutive crops, the exhausted earth requires sun, air and repose. It is left uncultivated, and the humidity produces a spontaneous growth of plants adapted to the nature of the soil; it is manured, then only, on the new sward, and during two years an abundant but coarse crop of hay is gathered from it."

This rotation is not cited, as offering an example, for imitation, but merely to show the necessity which, in a country so fertile as Lombardy, and where there is a command of water, is deemed to exist, of manuring, and of resorting to a dry culture and a change of plants in the cultivation of rice.

In the valley of the Arno, in Tuscany, the following course of four years is a common one:—1st year.—Wheat, followed in autumn by Haricot Beans, intermixed with Indian Corn.

2d year.—Wheat, followed by Lupins.

3d year.—Wheat, followed by a forage crop.

4th year.—Indian Corn, millet or sorgho.

Being seven crops in four years, of which four are exhausting and three ameliorating. We have in this example an admirable instance of great productiveness, resulting from the introduction of secondary crops, which, at the same time happily interrupt the succession of the exhausting plants. It is owing to the latter cause, to great natural fertility, the highest cultivation, and to irrigation, that the soil is not exhausted under this rotation, which has been adopted, to meet the exigencies of a very dense population.

I will detain the society, to present to their consideration, only one more example of rotation, drawn from the vicinity of Sorrento, in the kingdom of Naples, in which our great staple is introduced.

1st year.—Indian corn, manured.

2d year.—Wheat, followed by beans.

3d year.—Cotton.

4th year.—Wheat, followed by purple clover.

5th year.—Melons, followed by legumes.

Producing eight crops in five years. "It is impossible," says Chateaubriand, "to make a better arrangement of the various crops. The nature of their vegetation, and the various cultures which they require, alternately rest and prepare the soil, of which the fertility is preserved by this variety, for the production of every thing which the earth can render to human industry."

ON PLANTING.—The sheepkeeper turns his capital once in a week or a month. The farmer turns his money once in a year, but the forest planter must discard the commercial maxim, a small profit and quick return; for he can scarcely turn his capital once in his lifetime. Still, however, nothing can pay better than the planting of waste lands with forest trees. Oaks, pines, and willows, will give more profit than ferns, heath, and rushes, and a practical man with four laborers under him could superintend 500 acres. A man cannot amass a large property for his children by a small outlay so surely as by planting.

MAMMOTH COTTON STALK.—The dry stalk of a cotton plant, grown in Texas the last season, has been left at our office, by Capt. Dismoor, which is really a curiosity. It measures 15 feet in length, and eight inches in circumference, near the root, decreasing gradually to the top.—*Mobile Register.*

HORTICULTURE.

CULTURE OF ASPARAGUS.

Normanstone, near Georgetown, D. C. }
Mr. SMITH: March 12, 1833. }

I think I could suggest to friend Sinclair a better mode of raising asparagus, than that pointed out in his communication in your paper of the 15th ult.

In order to have strong plants, a point very essential to ensure fine asparagus, the seed bed should be dug to the full depth of a spade, say 12 inches, and the earth thrown out, then filled with good rotten manure, on which the seed may be sown, and covered two or three inches with the lightest and best of the soil; and as it is of vital importance to keep the seed beds carefully clear of weeds, this will be facilitated by having them quite narrow, so as to be able to reach from each side without the necessity of treading or pressing on them. The fall, so soon as the seeds are quite ripe, is the best time to sow them, or as early as possible in the spring, the seed should be entirely cleaned of the skin and pulp, a very easy operation. This mode of sowing ensures strong good plants which when only yearlings, will be quite as ready to plant in their permanent beds, as two year old plants generally are.

In laying out the beds, which need not exceed three feet six inches wide, dig a trench in the middle, two feet in width and fifteen inches in depth, which fill with good short manure, and plant thereon two rows only: the earth thrown out will be sufficient to cover them and to raise the whole bed uniformly, as high as needed above the alleys. These narrow beds have the same advantage as the narrow seed beds for clearing and cutting; and I am not sure that even single rows would not be preferable. It is impossible when there are three or four rows in a bed (unless they be crowded too close to each other) to reach to cut or clean from either side without treading on the bed.

In the fall, the haulm should be cut off as soon as the seed pods begin to show indications of changing to ripeness, lest by awaiting the last powerful effort of nature, that of perfecting and maturing seed, the plant be weakened; on the other hand if cut earlier, and the season continue mild, there would be great risk of a fresh crop of heads being thrown up, which would equally exhaust the plant and destroy the hope of the succeeding season. The haulm should be dried for a few days and then tied up in sheaves, and secured for the very useful purpose of covering lettuce or other small plants through the winter, for which it is eminently fitted by its lightness, and warmth, without affording shelter to the ground mice to commit their ravages on the crop under its care.

In dressing the beds, I prefer, to the old mode of covering them with a coat of manure through the winter, to remove the soil from the roots, taking care not to injure the crowns, then fill well in with short manure and replace the soil over all; by this means none is wasted by evaporation, but all is at once applied on the very object of its application and the effort is to bring forward the crop full ten days earlier than in the usual course.

Some years ago being in Belgium, I observed in the neighborhood of Brussels that the gardeners were in the spring covering their asparagus beds with a thin layer of clay puddle which was smoothed over the surface, and formed a receipt of a coat of plaster of three-fourths to an inch in thickness. As far as I could make out from the want of mutual understanding of our respective languages, the intention was to prevent the heat coming too rapidly through the surface, and I supposed that the poor spirey dwindling sprays could never make way; and none but stout stems and which by the delay became more blanched, could emerge to day light, but whatever the purport, the produce was delicious, and far surpassed, as indeed all their vegetables do, any that I have met

with any where, not excepting even that raised at Chelsea, or the eastern shore of your state.

I submit these observations as my small contribution to your valuable periodical, and as hints to be improved upon by more experienced men than myself.
R. B.

LARGE PUMPKINS.—Mr. David Warren, of York county, Pennsylvania, advises the York County Farmer that he raised nine pumpkins, from one seed, during last season, the united weight of which was six hundred and ninety pounds. The largest of the nine weighed one hundred and two pounds, and the smallest forty-two pounds. "Beat this," says Mr. Warren, "and I will try it again."

RURAL ECONOMY.

PEN YOUR HOGS.

Mr. SMITH: Woodside, Del. March 15, 1833.

I have often been astonished to find it is the general plan with farmers to allow their hogs to run at large the most of the year, placing their crops in a constant liability to be injured by them, as the best of fencing is but a poor defence; for a bar being left out or a gutter washed by rain, easily gives them the opportunity of destroying a deal of the farmer's hard earned crops. But without any of these accidents, their loss in another way is much more than they may imagine; I mean in the article of manure, which all certainly will allow ought to be the aim and principal object to amass as much as possible in every possible manner; the manure made by these animals is of the very best kind, and by proper care a large quantity may be made by a few of them. Some object to it by saying the litter given to them might be as well used in the barn yard; but they must remember it is made at a time when our barn yards are without stock; and the pig pen is a convenient repository for all the rubbish you can accumulate, weeds from your garden and all weeds or coarse grass you can cut from any part of your grounds during the summer; also the rakings of your stubble ground the spring succeeding a crop of wheat and many other sources unnecessary to mention. A little earth spread over each layer of litter will be found a great advantage as it induces them to root among and stir it up which soon produces fermentation.

It would astonish any one, unless they have given it a trial, how much manure may be made in this way of the very best description. For instance, the past year I kept eighteen hogs, the cost of their feed (exclusive of corn while fattening) was \$2.00 per head, making a total of \$36.00. I have not a doubt I shall be able this spring to draw out of their pens over one hundred large three horse cart loads. Manure is now selling in Wilmington at \$1.25 per cart load, which at one hundred loads leaves a balance in favor of the hogs of \$89.00, without the expense of hauling it from Wilmington, a distance of three miles; the hauling of which would much more than cover the additional expense of tending them when kept up. I have a strong rack fixed in the pen similar to a sheep rack in which they get fresh grass three times a day; having which they require but little feed to keep them in good thriving order. As I am convenient to merchant mills, I get an article called sweepings which is sold for that purpose, consisting of corn meal, flour and the offals of the grain, this we mix with milk and water and give them for wash.

Let any one give this plan a fair trial and I am convinced they will never again allow their hogs to roam about, which not only appears slovenly but must keep them in constant fear of their breaking into the grain or other crops. If by these plain matter of facts I can induce any one to give it a trial, and thereby cause a slight improvement in agriculture, the end is gained, of
Respectfully, yours,
S.

SUMMARY.

Mean temperature at sunrise, 28.29.

Do. at midday, 39.32.

Mean for month, 33.80.

Range, 41°.

Maximum of temperature, 58° on 24th.

Minimum of temperature, 17° on 8th, 24th and 26th.

Warmest day, 47° on 20th.

Coldest day, 21.5 on 1st.

Temperature below 32° on twenty days.

Do. above 32° on eight days.

Wind west on twenty-three days.

Wind east on five days.

Rain on six days.

Snow or hail on five days.

Fair weather, eighteen days.

Cloudy and stormy, ten days.

Temperature compared with last month, 1.62° colder.

Temperature compared with same month last year.

1.17 colder.

The winds in this month were unusually high and very variable. The weather through the winter remarkably variable, though at no time very severe—the ground scarcely covered with snow at any time—till the last day of the month, when snow fell through the day and night five or six inches deep—sleighting continues good to March 7th.

MEMORANDA.

1st. Roads very muddy, much frozen, but not hard enough to bear a carriage. Cirrus clouds remarkably fine, in lines from west to east, north of the zenith, with patches in the south.

3d. A fine flock of meadow larks (*Sturnus ludovicianus*) near the academy, these seldom visit this neighborhood, though they are abundant along the

shores of the Delaware, further south, and are of great value, to graziers in destroying insects; especially grasshoppers (*Acerida verrucivara*, &c.) and crickets (*Acheta campestris*, &c.) which they eat in surprising quantities—this habit has induced some farmers to give them protection, and to forbid shooters molesting larks on their premises—it is time our agriculturists were more awake to the importance of cultivating the friendship of our beautiful feathered visitant, instead of permitting a cruel exterminating war to be waged against them.

12th and 13th. Storm from N. E. with much rain. 15th. A violent snow storm from N. E. from four to six inches deep, afforded a little poor sleighing the first this winter.

23d. A delightful morning, observed to day numerous blue birds (*Ampelis sialis*.) they seemed constantly to prefer the topmost twigs of the trees. It is a common saying with the country people, that when the blue birds set on the highest branches, we shall soon have colder weather, but if they prefer the lower parts of the tree the weather will be mild—also the flicker, or golden-winged woodpecker, (*Picus auratus*.) the cow blackbird, (*Icterus pecoris*), &c.

24th. In the evening the wind was S. W. 6, but shifted to N. W. and blew a perfect gale with snow, hail and rain, after a delightfully pleasant day—the storm continued till 9 P. M. when it cleared and became very cold; the temperature changed from 55° to 17° in less than eight hours.

25th. In the morning observed moles busy at work under the snow heaving up the ground, apparently seeking a shelter, after having been tempted out by the pleasant weather the day before.

26th. Snow all day and continued the next day.

CURIOUS EXPERIMENT ON A RATTLESNAKE.

The following curious facts, respecting the rattlesnake, are from a letter of Judge Samuel Woodruff, to Professor Silliman, in the last number of the American Journal of Science:

During the summer months of 1801, I resided in the northeastern part of the state of Ohio. Rattlesnakes were then very numerous in that region. I found the opinion universally prevalent, among the inhabitants there, that the leaves of the white ash are highly offensive to the rattlesnake. Several persons of respectability assured me that the rattlesnake was never found on land where the white ash grows; that it was the uniform practice among hunters, as well as others, whose business led them to traverse the woods in the summer months, to stuff their shoes and boots, and frequently their pockets also, with white ash leaves, as a preventive of the bite of the rattlesnake; and that they had never known or heard of any person being bitten who had used this precaution.

Some time in the month of August, I went with Mr. T. Kirtland, and Dr. C. Dutton, then residing at Poland, to the Mahoning, for the purpose of shooting deer, at a place where they were in the habit of coming to the river, to feed on the moss attached to the stones in the shoal water.—We took our watch station on an elevated part of the bank, fifteen or twenty yards from the edge of the water. About an hour after we commenced our watch, instead of a deer, we discovered a large rattlesnake, which, as it appeared, had left his den, in the rocks beneath us, and was slowly advancing across a smooth, narrow sand beach towards the water. Upon hearing our voices, or for some other cause, he stopped, and lay stretched out, with his head near the water. It occurred to me that an opportunity now offered to try the virtues of the white ash leaves. Requesting the gentleman to keep, in my absence, a watch over our object, I went immediately in search of the leaves, and on a piece of low ground, thirty or forty rods back from the river, I soon found, and by the aid of my hunting knife, procured a small white ash sapling, eight or ten feet in length; and, with a view to make the experiment more satisfactory, I cut another sapling of the sugar maple, and with these *reeds* returned to the scene of action. In order to cut off a retreat to his den, I approached the snake in his rear. As soon as I came within about seven or eight feet of him, he quietly threw his body into a coil, elevated his head eight or ten inches, and brandishing his tongue, gave notice of preparation for combat.

I first presented him the white ash, placing the leaves upon his body. He instantly dropped his head to the ground, unrolled his coil, rolled over upon his back, writhed and twisted his whole body into every form but that of a coil, and appeared to be in great anguish. Satisfied with the trial thus far made, I laid by the white ash. The rattlesnake immediately righted, and placed himself in the same menacing attitude as before described. I now presented him the sugar maple. He moved in a moment, striking his head into a tuft of the leaves, with all the malice of the under hand; and the next moment he coiled and lanced again, drawing his whole length at each effort with the swiftness of an arrow. After repeating this several times, I again changed his *fire*, and presented him the white ash. He immediately *dropped his peak*, stretched himself on his back in the same manner as at the first application. It was then proposed to try what effect might be produced upon his temper and courage by a little flogging with the white ash. This was administered. But instead of arousing him to resentment, it served only to increase his troubles.—As the flogging grew more severe, the snake frequently struck his head into the sand as far as he could thrust it, seeming desirous to bore his way into the earth and rid himself of his unwelcome visitors.

Being now convinced that the experiment was a satisfactory one, and fairly conducted on both sides,

we deemed it unnecessary to take his life after he had contributed so much to gratify our curiosity; and so we took our leave of the rattlesnake, with feelings as friendly at least as those with which we commenced our acquaintance with him, and left him to return at leisure to his den.

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals, — viz:

A Bull 5 years old, full blood, for	\$ 300
Do 3 " " Do "	300
Do 2 " " Do "	250
Do 1½ " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each.

Half Blood and upwards. — A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenth Durham Shorthorn, very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$160.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address I. I. HITCHCOCK.
Amer. Far. Office.

BENE SEED.

Just received at the American Farmer Office and Seed Store, a supply of fresh seed of the Bene Plant, so celebrated for its medicinal virtues in the cure of the summer or bowel complaint of children.

GRAPEVINES AND CUTTINGS.

For sale at the American Farmer Office and Seed Store, the following, which can be sent safely any distance:

ROOTED VINIS.

Herbemont's Madeira, two years old, 33 cents each, \$3.50 per dozen, or \$25 per hundred.

Isabella, very fine roots, two years old, 37½ cts. each, or \$4.00 per dozen.

White Scuppernon, one year old 25 cents each, or \$2.50 per dozen.

CUTTINGS.

Cunningham, finest native grape, both for wine and table, 12½ cents each, \$1.25 per dozen, or \$8 per hundred.

Woodson, very fine do. do. same price.

[For description of these, see American Farmer, Vol. xiv. No. 33.]

Norton's Virginia Seedling, fine, same price.

Cuttings of the Isabella, Muscadell, and Golden Chaselas, 50 cents per dozen. I. I. HITCHCOCK.

HERBEMONT ON THE VINE AND WINE MAKING

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States. By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents.

GARDEN SEEDS.

Received by the ship *Gulnare* my usual supply of first rate GARDEN SEEDS, which I offer for sale, wholesale and retail, consisting of the various kinds of Peas, Beans, Cabbage, Radish, Carrot, Onion, Beet, Turnip, &c.

All that I need say to my customers in commendation of these Seeds is that they were raised by the same gentleman that for a number of years hath supplied those Seeds they have found so genuine, and that the present parcel has come to hand in fine order. To those unacquainted with these Seeds I would observe, that they are raised by a person of very great horticultural experience, and as I receive them direct from him there never has been or will be any mistake or deception in quality or kind of Seed. It is a fact well known to every experienced gardener, that the first rate English Seed produces incomparably better crops than can be obtained from Seeds raised in this country.

These Seeds are for sale at No. 78 Ensor (late Bridge) street, O. T. 2d door above the Town Clock.

SAMUEL AULT.

N. B. Orders from a distance with remittances (post age paid,) will be promptly attended to, if directed as above. Ma. 23—11

REMOVAL.

SINCLAIR & MOORE have removed their AGRICULTURAL REPOSITORY to the CORNER OF PRATT AND LIGHT STREETS, HEAD OF THE BASIN, where they offer for sale a general assortment of IMPLEMENTS, FEEDS, FRUIT TREES, &c. &c. Feb. 22.

SINCLAIR AND MOORE'S NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Bushes, (among which is the much admired Greville,) double Altheas, Honeysuckles, Corcorus, Lilacs, Snowberry and Buffalo Berry Trees, Chinese Alanthus, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets. Feb. 22.

AGRICULTURAL IMPLEMENT AND SEED STORE.

J. S. EASTMAN, No. 36 west Pratt-st. keeps constantly on hand a supply of his Patent Cylindrical Straw Cutters of the various sizes, which he will warrant to cut as much, according to their size, and to be decidedly superior in every respect to any similar machine made in this country.

Also, very superior Rag Cutters, for the use of Paper Mills.

Gideon Davis' Improved Patent Ploughs, of all sizes, with wrought and cast shares, and all kinds of castings for those ploughs by the piece or by the ton, as likewise for horse powers, on as reasonable terms as can be had elsewhere.

Wheat Fans, Corn Shellers, Threshing Machines, Harrows, Cultivators, &c. Likewise superior Cast Steel Axes, Hay and Manure Forks, and Scythe Snaths at wholesale and retail. Shovels, Spades, Hoes, &c. &c. and all repairs done at short notice.

Field and Garden Seeds. Such Grass Seeds as are in market will be kept for sale. My assortment of Garden Seeds is not so extensive as advertised by some, but such as I shall offer for sale may be relied on as genuine. The following I could furnish at wholesale, viz: Superior Early York Cabbage, and Long Scarlet Radish Seeds, and Early Frame Peas, the latter raised by Richard Cromwell, Esq.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—A slight improvement has taken place in flour and wheat, owing to the opening of the spring business. The wagon price of Howard street flour is \$5 25; we heard of a few sales at higher rates, but they were for particular brands. Sales from stores have been made at our quotations. There is not much doing in grain, but what transactions have taken place have been within our quotations.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15 00; yellow and red, 9.99 a 15.00; yellow, 16 00 a 20.00.—Fine yellow, 18.00 a 26.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3 50 a 8 70. The inspections of the week comprise 42 hds. Md.; 30 lds. Ken.; and 1 hhd. Ohio—total 73 hds.

FLOUR—best white wheat family \$6.75 a 7.25; super Howard-street, 5.44 a 5.50; city mills, 5.37½ a —; city mills extra 5.50 a —;—CORN MEAL bbl 3 50;—GRAIN, best wheat, 1.05 a 1.10; white do — a —;—CORN, white, 58 a 60, yellow, 58 a 60;—RYE, 65 a 68 —OATS, 37 a 40 —BEANS, 75 a 80 —PEAS, 65 a 70 —CLOVER-SEED 5.00 a ——TIMOTHY, — a ——ORCHARD GRASS 2.00 a 2.25.—Tall Meadow Oat Grass 2.00 a 2.50—Herd's, 75 a 87½—Lucerne — a 37½ lb.—BARLEY—FLAXSEED 1.50 a 1.62—COTTON, Va. 10 a 12—Lou. 12 a 13—Alab. 10 a 11½—Tenn. 10 a 12; N. THE FARMER.

BALTIMORE, FRIDAY, MARCH 29, 1833.

NEW YORK STATE AGRICULTURAL SOCIETY.—We have heretofore neglected to notice the establishment of a State Agricultural Society in the state of New York. The plan of the society is a grand and imposing one. It contemplates the establishment of county societies as branches, and its officers are selected from among the *practical* husbandmen of the different counties exclusively. This we deem an important feature in its plan, and one essentially necessary to its permanence and usefulness; for practical men will not submit to take lessons on their professional concerns from those who are at best mere theorists, much less from those who are neither practically nor theoretically acquainted with the subject on which they pretend to give instruction. We have received a pamphlet from the society containing a number of valuable papers, which we shall occasionally lay before our readers. The following report on the subject of a farm school, will be read with interest, and we shall therefore make no apology for occupying an editorial page with it, to the exclusion of less interesting matter.

At a meeting of the New York State Agricultural Society, held at the Capitol, in the city of Albany, February 14, 1833.

AMERSE SPENCER, *Vice President*, in the chair.
JESSE BUEL, *Secretary* P. T.

Mr. Buel, in behalf of the committee appointed to report on the subject of an Agricultural School, read the following report, which was accepted:

The committee appointed at the first meeting of the society, to report a plan for an Agricultural School, with an estimate of the expense necessary to establish and put the same into operation; together with their views of such an establishment, beg leave to submit the following

REPORT.

The main objects of the proposed school are, to impart to agriculture the efficient aid of the sciences, and to furnish it with the best models of practice;—to teach, simultaneously, in the period of youth devoted to academic studies, the practical operations of husbandry, and such branches of useful knowledge as may tend to elevate its character, and increase its products. The *plan*, therefore, should embrace,—

1. A FARM, of sufficient extent to afford room for the diversified operations of tillage, cattle and sheep husbandry, and of orcharding and gardening—on a scale that will admit a fair comparison being made of crops, of breeds of cattle and sheep, and of the varieties of hardy fruits;—and sufficiently diversified in soil and surface as to admit of satisfactory experiments.

2. A FARM HOUSE AND FARM BUILDINGS, which may serve as models of convenience, taste and economy, and accommodate the head farmer and his assistants;

3. A SCHOOL BUILDING, for the accommodation of teachers and scholars;

4. A LIBRARY AND PHILO-SOPHICAL APPARATUS;

5. STOCK AND IMPLEMENTS for the farm; and,

6. SHOPS for the construction of farm implements and machinery, for the use of the farm; for the illustration of mechanical science, and to afford practical instructions to the pupils in mechanics.

These items of expense, which may be considered preliminary and permanent, together with the cost of the furniture required for the school building, are estimated at \$7,500.

1. The plan of education might embrace,—Practical instructions in the various operations and labors of the farm, the garden, the orchards and the shops; and,

2. The study of the natural sciences generally, mathematics, mechanics, chemistry and drawing, so far as these may conduce or become subservient to agricultural improvement,—together with such other branches of knowledge as will qualify the students for the higher duties of civil life,—such as will fit them to become independent electors, discreet jurors, faithful magistrates, and wise legislators.

As prerequisites to admission to the school, the pupils might be required to possess a good common school education, to be at least fourteen years of age, and of good moral character. Four years might constitute a course of studies; and the internal regulations and police of the school might be conformed, in a measure, to those of our military academy.

A department of the farm should be set apart for experiments in husbandry, and the details and results of these experiments accurately registered. The garden and the orchard should contain all the good hardy fruits, and specimens of all hardy plants, that may be useful on the farm, in the arts, in commerce, or that are ornamental,—in order that the relative value of different species and varieties may be determined, and their mode of culture, and process of curing, taught to the pupils,—and the approved kinds furnished for public distribution.

To put the school into operation there will be required,—a principal, professors and teachers,—a steward and servants, for the school;

A manager, laborers and assistants for the farm;

Machinists and assistants for the shops; and

A practical and scientific manager for the garden and orchard.

The number of officers and assistants which will be required, must depend upon contingencies; and of course the committee do not pretend to state with precision, in their estimate, the amount of their salaries and pay.

The proceeds of the school and the farm may be expected to increase for some years, and will materially depend on the terms of tuition. The committee have assumed, as reasonable data, that the number of pupils would average 200, and the average produce of the farm amount to \$4,000 per annum, for the first four years. Upon the assumed data, then, the estimate would exhibit the following result.

PRELIMINARY EXPENSES.

Farm of 100 acres, at \$50,	\$12,000
Farm buildings,	6,000
School buildings,	25,000
Library and apparatus,	7,500
Stock and implements,	3,150
Shops and tools,	1,250
Furniture for school,	1,150
Incidental,	1,500
Total preliminary expense,	\$57,550

ANNUAL EXPENSE.

Salaries of officers and teachers of the school,	\$5,100
Do. of manager and laborers on farm,	1,000
Do. of machinists,	600
Do. of gardener,	300
Expense of boarding 200 pupils at \$1.50 per week,	14,400
Servants for the establishment,	2,000
	23,400

Estimated annual expense, . . . \$30,950

The Annual Receipts are computed as follows:

Board and tuition of 200 pupils, at \$150 per annum,	\$30,000
Produce of farm,	4,000
	\$34,000

Thus the total expense of establishing the school, and of maintaining it the first year, is estimated at \$80,550, and the income, after the first year, it is believed, will be amply sufficient to defray all expenses.

Yet to meet contingencies that may occur, and to make up for any deficiency in the estimate, the committee think that an appropriation of \$100,000, the surplus to be invested for the benefit of the institution, will ensure usefulness and permanency to the school, and prove amply sufficient to meet all its wants. This sum, if equalized among the population of the state, would operate as a tax of about *five cents* to each inhabitant.

(From the Genesee Farmer.)

PRICKLEY ASH FOR HEDGES.

Lockport, 2 mo. 29, 1833.

I have been of the opinion that the Fraxinus, Prickly Ash, or toothache tree, as it is familiarly called, would make a hedge in all respects as good, if not superior, to any shrub now in use either here or in Europe. It, to my knowledge, thrives well on a clayey, or even sandy or gravelly soils, but best on rich moist bottom land, and is about as hard to subdue as are elders. As far as my knowledge extends, it is not infested with lice or worms, which are so destructive to the English thorn in our country. No blight affects it that I know. Has any one made trial of it for the above purpose? If so, will they please to favor us with the result of their experiment, and oblige one of the public, and perhaps many.

I. W. SMITH.

FIRE PROOF AND WATER PROOF CEMENT.—To half a pint of milk put an equal quantity of vinegar in order to curdle it, then separate the curd from the whey and mix it with the white of four or five eggs, beating the whole together; when it is well mixed, add a little quick-lime passed through a sieve, until it has acquired the consistence of a thick paste. With this cement, broken vessels, and cracks of all kinds may be mended. It dries quickly and resists the action of fire and water.

FOREIGN MARKETS.

LIVERPOOL, Saturday Morning, Feb 23.

We have now closed the fourth dull week in our Cotton market. The trade have continued to buy sparingly, and still seem determined to pursue the same course, in order to break down our prices. So far their success has been partial only. An eighth per lb. has, in several instances, been conceded to them; but these concessions not being yet general, we venture again to resume our former quotations for all kinds of American Cotton. Surat Cotton, however, went off yesterday by public sale at lower prices.

The whole purchased by the trade, except 500 bales on speculation. The chief sales in Upland have been from 7 to 7½, in Orleans from 8 1-3 to 7½, and in Tennessee from 6 8-9 to 6 7 8. [Strictly speaking we ought to take 1-8 off our quotations pretty generally, but we let them rest, till we see what another week may do for our market.]

LIVERPOOL, Feb. 18.

Our Cotton market remains rather flat, with little or no change in prices. The sales of the week were 15,530 bales.

LIVERPOOL, Feb. 23.

Cotton.—Sales of the week 11 180 bales, 500 on speculation; of which were 380 Sea Island 114 to 16d; 10 Stained 7½; 4150 Upland 6½ to 7½—12 at 8d; 2720 Orleans 6½ a 8½—17 at 9d; 950 Alabama 6½ a 7 3 8d.

There has been some fluctuation in our corn market, but prices remain pretty near the same point at which they stood some days ago. We quote United States as before—Sweet in bond at 21s to 25s and sour do. at 16s to 17s per bbl.

The sales of cotton this day about 2500 bales; no change in prices.

AGRICULTURE.

(From the Southern Agriculturist.)

ACCOUNT OF AN AGRICULTURAL EXCURSION,
Made into the South of Georgia, in the winter of 1832.

BY THE EDITOR.

It is one of the unfortunate characteristics of our climate, that danger attends all excursions into those parts of our country where the soil is sufficiently rich to reward the labors of the husbandman; hence, it is almost impossible in some parts for even the proprietor to superintend his concerns throughout the year, and consequently, at least for five months, he is under the necessity of confining himself to giving orders based on the reports of others, or at most, on an occasional and hasty inspection. There can be no doubt but this state of things materially retards our progress towards improvements, and gives to our plantations that air of careless negligence, which may be pardonable in a newly settled country, but which ought long since to have passed away from all of the Atlantic states. But although it is extremely dangerous to reside on a large majority of our plantations, yet fortunately it has been discovered, that settlements can be made in our pinelands, to which the planters can resort during summer and enjoy all the blessings of health, whilst at the same time they can visit their plantations sufficiently often to inspect all the operations carried on, and direct and control the whole. Such settlements of late have become numerous, and our planters have experienced much benefit from resorting to them. But whilst the planter residing at one of these pineland settlements, has it in his power to visit his own plantation and those in the neighborhood, yet he is confined by the inhospitality of our climate from extending his excursions into other sections of the country during this period, and seeing the operations as carried on there. Thus does he lose the opportunity of gaining much useful information, which his personal inspection, would enable him to obtain. All these visits, therefore, necessarily take place in the winter or early in the spring, at which time there is comparatively little to be seen and few occurrences take place to suggest new ideas or improvements.

Should a stranger visit us, he must do so at that season, of all others, the least inviting in the country, and when he does come, he sees but little from which he can form any opinion of our state of agriculture. It is only those who having been brought up among such scenes, and been long familiar with them, can detect differences in the modes of culture, or some of the other operations of the place, which may cause them to institute inquiries, and enable them to compare these with those they have been accustomed to. Still this is far from being satisfactory; yet, being the best we can do, we must rest satisfied with it. In the agricultural excursions which we have made, we have labored under some of these disadvantages, and if, therefore, they should not convey all the information which might be expected, we hope our readers will bear in mind, the seasons at which they were made, and the impossibility of making them at any other.

On the 24th of November, 1832, we embarked on board of the steamboat William Seabrook, and after a pleasant passage, arrived at Savannah the next morning at eight o'clock. We remained but one day at Savannah, intending to give this place a better examination on our return. Early on Monday morning we took the stage, and by evening were safely lodged in Darien. We saw nothing on this route worthy of special note. The road was most excellent, passing over a variety of soils.

From Darien we proceeded to "Hopeton," the residence of J. Hamilton Couper, Esq. and paid a visit to "Champney's and Butler's Islands." From whence

we proceeded to "Sapello Island," the residence of Thomas Spalding, Esq. and with a description of which place we intend commencing the account of this excursion, leaving the other places until our return, as we again visited each of them. A boat and hands having been kindly sent for us, we proceeded on the 4th of December, from the residence of Dr. Tunno, on Champney's Island to Sapello, a distance of fourteen miles, and which we reached a little after 12 o'clock. We ought, perhaps, to premise, that the Altamaha river for some distance from its mouth, is filled with islands, some of them of considerable magnitude, and most of them extremely rich. The river is wide even opposite Darien, or rather it is divided into several branches, each of which might be considered a good sized river. Darien is situated on the northern branch, and most of the rice plantations, which we shall have occasion to notice are either immediately opposite, (embracing all the branches of the river,) or a little above. Below Darien, the action of the sea water is perceptible. The islands are soon passed and nothing but mud banks, covered at first with coarse grass, peculiar to brackish water, and finally terminating in marsh, are to be met with. At its mouth the river is very wide from the northern to the southern side, which we shall have occasion to notice hereafter. The afternoon and evening of the day of our arrival, was passed in most agreeable conversation with Mr. Spalding, whom we were glad to find without company. The next morning we rode out to view the southern part of the island, occupied by Mr. Spalding, who owns a large portion of the island; the remainder is owned and occupied by Dr. Rogers, whose plantation we had not the time to visit.

Mr. Spalding's residence is situated at the extreme south end of the island, in a beautiful grove of live oaks. On passing from among these, the spectator who visits the island for the first time is struck with the peculiar appearance presented to him, instead of meeting with a thick growth of trees, such as is common on all sea islands on our coast, he suddenly finds himself in a prairie, extending to the north almost as far as can be seen, skirted on the east and west with a low growth of live oaks and other trees, whilst the intermediate space is broken here and there, with small clusters of trees. This island is situated at the mouth of the northern branch of the Altamaha river, and is about ten miles long and two and a half miles in its widest part; it contains about ten thousand acres above the flowing of the tide, made up of hummock lands, covered with live oak and pine, to the extent of two or three thousand acres, and at least three thousand acres of prairie lands, such as we have described, and which are considered fertile and are cultivated in cotton and corn. This land appears to be made up of what seems to be a rich vegetable mold, in some places, six feet deep, resting on white sand. In its uncultivated state, it is thickly covered with various grasses and affords a fine pasturage; but when under culture it becomes so friable, that it is impossible to ride in the fields, except in the tracks beaten hard, by the negroes passing and repassing. The attempt to ride in any other part would be attended with great inconvenience if not danger, as the horse would immediately bog. We are not aware whether this is the case during summer, when the soil has been dried by the sun, but was certainly the case in those fields we rode in, which were at the time somewhat, in a moist state.

In our morning ride we passed through a considerable portion of this prairie land, and visited the fields of sugar cane and cotton, and the establishment for manufacturing sugar, consisting of mill, boiling and curing houses, all made of tabby. These are all at a distance of at least three miles from the mansion, with the exception of a small cotton field near the house. The intermediate space is principally prairie lands. On our return, we retired to the library, and as the day was disagreeable, we employed ourselves

in obtaining the following particulars from Mr. Spalding, which we noted down at the time.

"The agricultural products of this island, are cotton, sugar, corn, &c. On this island was the first cultivation of cane for the production of sugar within the Atlantic states—here the growth of cane for that purpose was begun in 1806, and has been continued ever since. The product of sugar could not be taken for the last twenty years above 700 pounds. In cultivating cane, the land is formed into low ridges, occupying the space of five feet; a broad trench is opened along the centre of the ridge, into which are laid two continuous strings of cane, four or five inches apart. It is covered two inches deep. As early in March as possible, (the time of planting having been in January and February,) the earth is loosened over the cane plants, so as to give greater facility in their coming up; and the carts having been employed after the completion of the crop, in carrying out and depositing in every quarter of an acre, such manure as may have been gleaned from the cattle pens and other ways, the smaller hands, if there has been any interval of time for the operation, are employed in strewing some small portions of manure, over the ridges ahead of those employed in loosening the soil. If we have not had time to perform this operation, before the first stirring, we rarely can accomplish it before the first of June, for our other crops begin to press upon us soon after the beginning of March. In preparing the cane land and planting it, we may take in round numbers for listing, bedding and planting, sixteen laborers to the acre, exclusive of a few old hands employed in stripping the cane plants and examining them, and the carters who are employed in taking them from the field where they have been deposited in autumn, to those fields which are now prepared for their reception. It may be understood in the general, that such is the temperature of the climate of Sapello, that it is the tops of the canes that have been previously manufactured and not the bodies that are employed for seed of the next year. This course is not generally pursued in Georgia, elsewhere than on Sapello, and is sometimes attended with loss even there, as was the case last winter. We give the sugar cane after the first operation in spring, of loosening the soil over it, the same number of hoeings we give our cotton fields, with the same expense of labor. This, however, is a bad course, the plough appears to be peculiarly adapted to the sugar cane, it opens and pulverizes the land at that season when it particularly requires it, much more radically than the hoe can do; local causes have prevented its introduction on this island.

"The cane juice has generally reached seven degrees of Beaume's hydrometer by the first of November, the blue ribband cane sometimes by the fifteenth of October. Whenever this is the case, your harvest should begin, the earlier the better, because the sooner you begin, the more time you have for the deliberate manufacture of your sugar, a matter of no small moment in the operation, and again, because severe frost sometimes deteriorates your juices from the seventeenth to the twenty-fourth of December. Fifty hands are employed per diem, in taking in and manufacturing from two to three acres of cane, according to its qualities; twenty hands are employed in stripping, ten hands in chopping or cutting down, ten hands with carts and loading of carts, and about ten hands about the mill and boiling house, of course the carters and out-hands render some assistance at night to those in the boiling house.

"Having found from long experience that a vertical cattle mill would not express the juices from the blue cane sufficiently, and not finding it convenient to procure a steam engine for the purpose, it was determined to erect a horizontal water mill, excavating for the purpose about five acres of marsh land, eighteen inches below the surface of high water, so as to be able to work with neap-tide, a few hours. This mill is connected to the water-wheel simply by a coup-

ling box, and will be all sufficient in common seasons, to take off from one hundred to one hundred and fifty acres of canes; this mill with its coupling apparatus, was delivered from the West point foundry, for twelve hundred and eighty-six dollars, payable in six months.

"There is nothing new to be added on the subject of preparing sugar to what has been already written. We are in hopes of improvement, but must wait for the result. It may, however, be interesting to know, that the sugar cane has travelled up the Altamaha river, and its tributary streams from Darien to Milledgeville, and from Darien to Macon, until every log house in this place has its sweets in abundance. However poor the individual may be, however limited his labors, some portion of this labor is set apart for this purpose. His little wooden mill and his pots set in clay; give him comforts which a few years back he little dreamt of. You may sometimes see the younger branches of the family at the end of a long lever turning the mill, while the elder are supplying it with cane, carrying away the juices and boiling it into syrup or sugar. A few years back small stills were common to be seen through the country; the peach orchard being almost the only object of luxury within their reach, now the still has given place to the sugar mill and sugar boiler, and the exchange must assuredly be beneficial to the people."

It is very gratifying to learn that the sugar cane has extended so far, and that it is likely to prove so beneficial as we are informed it is. The cane is cultivated, we understand, to a considerable extent, in the interior of Georgia, commencing from the sea-board; that is, scarcely a farmer is now found, who has not a small patch—even the pine land, if well manured, produces sugar of an excellent quality. We beg to be understood, however, as stating that it is not grown as a crop, but merely to supply their own wants, for this purpose it can be cultivated, but would be a losing business if attempted on a large scale for market.

Mr. Spalding has partly erected, and will have in operation during the next season, a set of works for boiling sugar in vacuum, which will enable him to manufacture it of a superior quality, as it has been satisfactorily ascertained, that the improvement, by this process is very great.

The varieties of cane cultivated on this island are the red (sometimes called the "blue") ribband, the yellow ribband, and the Otahettie. The first yields the richest juice, but is so hard as not to be easily crushed, and therefore wooden rollers cannot express all the juice it contains. The second yields more readily to pressure, but is so tender as to be easily destroyed by frosts; the third yields more juice than these, but contains less saccharine matter than either. Mr. Spalding having communicated through the *Agric. Cultivator*, at different periods his mode of manufacturing sugar, we will not detail it here, but refer our readers to these communications.

In the course of conversation, Mr. Spalding gave us the following account of the early culture of sea island cotton, and his present mode.

"Having been an eye witness, although very young, to the first introduction of long staple cotton into the United States, the changes the cultivation has gone through, are distinctly in remembrance. The cotton plant growing large, particularly on its first introduction into new soil, it was believed that it required great space to extend its limbs in, and to ripen and perfect its fruit. It was not known, that like all other oily seeds, vegetation is a little doubtful, and the plant when first coming up peculiarly tender and subject to many accidents. Unaware of these circumstances, the first cultivators deposited their seed in holes made on the surface of the fields at from five to eight feet each way. The consequence was, that even in the best soils scarce a fourth of the fields were covered with vegetation—the crops could in the nature of things under such circumstances be, but

very small. The ridge husbandry was but little known in any country at that time; in truth, modern agriculture owes its introduction to Tull, but his books and his system passed but slowly through his own country, and reached this at a still later period. The first application of the ridge husbandry to cotton ever remembered, was by Mr. Couper and Mr. Spalding the elder, of St. Simon's, and at St. Simon's. Still, although more of the seeds deposited in the earth grew, the old prejudice, of the plants requiring great space remained, and the product from even the best lands was limited. Accident brought a Bahama planter in the year 1794, to Georgia, he was a respectable kindly old man, who wintered with some of the cotton planters of that period. He was advising all of them to plant their cotton a great deal thicker; none of them, however, would take his advice or opinion, except a very young man commencing his operations on the south end of St. Simon's Island, who adopted it in its fullest extent—he drilled his cotton along the ridge; he left the stalks to stand at every six inches; he adopted the West India mode, and tilled it at from twelve to sixteen inches in height. The soil was very fine and new; the season was favorable; the crop was limited to sixty-five acres;—the result was three hundred and forty-one pounds of clean cotton to the acre. The revolution in the culture of cotton was wrought, every planter on St. Simon's Island followed the example of drilling, and leaving the plants to stand within six or eight inches in the row. From that period, viz. 1795, the same system has been pursued on St. Simon's, with, perhaps, as great results as to the quantity of cotton, as has been met with in any other part of the southern states.

"The cultivation on Sapello does not differ materially from the course that was pursued on St. Simon's; perhaps the ridges are made a little higher than they usually are elsewhere. The only novelty in the cultivation on has been in making the ridges in prairie or low lands, permanent and unchangeable for a series of years. The cultivation in that description of land is continuous, alternate rows of corn and cotton occupying the field, and the corn succeeding to the cotton alternately each successive year. No one ridge, therefore, is occupied by corn or cotton more than one year; and where the soils are rich and deep enough, whether they be the clays of our river lands, or the vegetable deposits to be found in our prairies or swamps, the system appears equally available, and in either of those lands without some extraordinary cause intervening, twenty bushels of corn, and one hundred and fifty pounds of cotton might reasonably be expected from the acre—neither the growth of the corn or the cotton, has been sensibly affected, either in the river or the prairie lands, by the beds having continued permanent for eight years, while much labor is unquestionably saved, by being exempt from throwing up of heavy ridges every spring. But this is not all, the lands from being turned over every year, whether they be clays of the river or the vegetable molds of the prairie, become too light and too easily washed down, and waste away by the heavy rains of summer, and as it is believed, more readily produce blue cotton, or large stalks without pods. Our operations on these lands is in the spring, to list down as light as possible the weeds that spring up in the months of February and March, so as to clean and bare the ridge. The ridge is then carefully trenched, and whether planted in corn or cotton, the seeds are dropped along this trench and covered over and trod down carefully with the foot. If the cotton grows very luxuriantly in the land, it is thinned down to about a stalk in every ten inches. The corn is left, if it can be done at ten inches apart in the trench, so that we have in fine, quite as many stalks of corn for our half crop as planters generally leave for their whole. But we have great evils to dread in both these descriptions of lands in setting our crops in the spring, the cut-worm as regards cot-

ton, and the cut-worm and the rats as regards corn. The best remedy found for both of these evils has been soaking the seeds of both corn and cotton, to give them as quick a germination as possible, then allowing them simply to dry, pouring over both the cotton seed and the corn, a mixture of lime water, stirred up into a whitewash. When this operation has been well performed so as to coat over the seeds with the whitewash, we have thought it almost a radical remedy, but it requires care in the operation, or it is in a great measure useless. As early as possible after the corn and cotton have reached three or four leaves, we dress up with care our ridges, cleaning up the intervals. Upon lands of this description, though commonly planted a little later than higher lands, the period of cleaning and hoeing ceases at the same time, which is with us generally about the first week in July."

The cotton receives four hoeings, not including the drawing down preparatory to planting—they are all light, never deep and always upwards—the top of the ridges or beds are wide, and the plants instead of being placed in straight rows, (as is usual in South Carolina,) are scattered over the whole surface, and thinned out to from six to twelve inches, leaving them still without regularity. The thinnings are not begun before the plants are about six inches high; but when commenced are continued until the plants are left at the distance intended; care is taken that the final thinning shall not take place until the heavy rains in May have set in, sometimes it is not finished until the first of June. On the prairie lands, the growth of the cotton is from four to eight feet high—it is lower on the hummock lands, which are quite sandy. The finest quality is produced on the former.

Mr. Spalding keeps on this island four hundred and fifty head of cattle, of which ninety are working oxen. These have been regularly herded during the day, and penned at night for the last ten years. The manure thus acquired is all applied to the sugar cane crop. The oxen were formerly used for the sugar mill and carting, but now are employed in the carts only. The other cattle are kept merely for plantation use. No sheep are now kept on the island. A large flock was brought down and promised well, but were all swept off by the gale of 1824, which overflowed the island, doing considerable damage, from which the land has not even yet recovered.

We were shown a large grove of orange trees, and some date trees, both in a very unpromising state. The orange trees had been very much injured by the severe frosts of 1830, '31 and '32, most of them have been killed to the surface of the ground, and many entirely. Previously they had promised well, and were generally about from fifteen to twenty feet high. One or two date trees only had grown to any size, the situation did not appear favorable to them.

On the afternoon of the 6th of December, we left Sapello, for St. Simon's Island, of which we will, in our next, give such information as we collected.

(To be continued.)

(From the Southern Agriculturist.)

ON MANURES.

Georgia, Columbia county, October 25, 1832.

Dear Sir,—A long and severe illness has placed it out of my power with any satisfaction to myself, to comply with your request at a more early period. Permit me, sir, to assure you, that no one feels a more lively interest in our agricultural prosperity than myself; and any thing that I can contribute that is calculated to aid your undertaking, is at your service. The only reluctance I feel in appearing in the character of an agricultural essayist, arises from the conviction of my want of experience on the subject. I hinted to you in a former communication, that I was a young planter, and consequently any observations that I may make are entitled to but little respect. For I think it is only after long and patient inquiry

that we may deem our results of sufficient importance to present to the consideration of the public. Premising this much, the following remarks can be taken for what they are worth.

Since the principal part of the grounds in the immediate neighborhood of the stables have been manured, I have thought it most advisable to place the cowpen on the field intended to be manured, to diminish the distance of carriage, which is a matter of considerable importance. This year I changed my cattle from their former to their present pen, about the middle of July. Two oxcarts and two wagons, with a proper number of hands were employed in collecting the first layer of leaves; since then, one wagon with three good hands have been almost constantly engaged in supplying the pen with leaves, swamp mud, &c. My plan in forming my compost is, to lay down first a layer of leaves and weeds, or corn stalks, and then a layer of mud. When it has been sufficiently saturated with the dung and urine of the stock, it is well mixed together by ploughing it once or twice, or even three times, if necessary, I then commence forming another layer, and so on. You may form some idea of the industry I have used in collecting my materials, when I inform you, that I have from the middle of July to the present time hauled into my cowpen, between fourteen and fifteen hundred wagon loads of leaves, and that at the same time I have kept my stables well littered. I have not as yet made use of cotton stalks, preferring corn stalks on account of their being of a more porous nature, and of course better calculated to absorb the moisture of the farm pen, but if greater industry should carry me beyond a sufficient supply of those materials, I shall undoubtedly resort to them; for I am confident but few things are better calculated to be substituted in their place.

The number of cattle penned, amount generally to forty-five head of cows, and seventy of sheep. My sheep, I have not been in the habit of penning till latterly, being under the impression that it was an injury to them. So far, however, I have discovered no injury to arise from it, and I will continue the practice until I have some positive evidence of its bad consequences; for their dung is of great importance, and if possible, they should be made to contribute their share in the improvement of the land. The oxen are stalled when at work, and well fed on pumpkins and pea vines, and when the labor is hard, a portion of corn meal is added, which is mixed up with cut stalks or rye straw. I have for the last two or three years stalled a few milch cows, treating them as I did my oxen; but the increase of milk was not as great as I expected, owing, I think, to a deficiency of succulent food. I am in hopes this winter to be able to remedy that evil, as I have three acres and a half of turnips, which at this time look very promising. One-half are ruta baga; they were drilled with a turnip drill on ridges two and a half feet apart, the ground having been previously put in good order by frequent ploughings, it was also well manured. My stables, as I have observed, I keep well littered; I clean them out every ten or twelve days, removing the dung immediately to the field, if it is ready for its reception. If not, I place it in rail pens in the yard. When horses are managed in this manner, the quantity of manure they make greatly exceeds the calculation of those who are in the habit of permitting them to stand month after month on their dung, without allowing them a fresh bed of straw or leaves. If the accumulation of manure is not a matter of sufficient importance, the life, health, and comfort of the animals deserve to be considered. For I am confident that many of the diseases which afflict horses are caused by the filthy or negligent manner in which they are kept. But every means in our power should be most diligently used to obtain the greatest quantity of manure. It has been emphatically called the farmer's "gold dust," and the distinguished author of "Arator," has declared that "the

agriculturist who expects to reap good crops from neglecting his manures, is equally a fanatic with the religionist, who expects heaven from neglecting his morals." "The true secret in carrying on this business to advantage, is to make it at once a distinct and separate concern, and one worthy of attention." It should be pursued with an energy equal to its importance; by no means delaying the cleaning out your stables to a rainy day, or permitting your cowpen, or hogpen, to suffer for the want of those materials, without an abundant supply of which, their dung is of but little profit.

The sterile aspect of the country, both in Georgia and South Carolina, indicates too truly our wretched system of agriculture, and the necessity of an immediate change if we wish to preserve the little remnant of fertility still left in our lands. It is useless to think of cultivating the grasses until our lands are rendered sufficiently good to produce them to advantage. It is equally useless to attempt to improve our stock by the introduction of fine animals, until we have pastures to support them, and the means of procuring for them, an ample supply of winter provisions. The basis then of all agricultural improvement, is a liberal system of manuring.

"Without fertility of soil, labor cannot be rendered effective or good crops obtained; for of what avail is any rotation of crops, the best contrived implements of husbandry, or the most perfect use of those implements, when applied to a barren soil. Fertility of soil is the capital from which all profits in agriculture must be derived. Manuring only, can recover this capital so much of which is already wasted by bad husbandry."

I know it has been frequently stated by writers on this subject, that slave labor is unfriendly to every thing like good tillage. By what train of reasoning they arrived at this very ingenious conclusion, I do not exactly recollect; but I think one of them points to our deserted old fields growing in broom sedge and briars as an evidence of the fact. I am ready to admit there are but too many proofs of our slovenly system of agriculture, and the one just mentioned stands at the head of the list; but it is no evidence of our inability to do better. Every thing depends upon the intelligence and industry of the individual who directs the labor; if he choose to employ a part of it in the making manure, I should be glad to know what is to prevent him. Five or six years past, when I first read the essays of Agricola, I was somewhat surprised at the assertion, that one acre could be as easily manured as one could be cleared. I say, I then marvelled at its absurdity; but greater experience in those matters has convinced me of the truth of the observation. If then, it is an admitted fact, and I believe it almost susceptible of demonstration, the question will at once present itself, why do we see so many flying to a new country to fell once more the forest? I will not attempt to describe the various motives by which no doubt they are actuated.

I, sir, have no permanent interest in the operations I have been directing, for the last few years; but it seems to me that if I were surrounded by those comforts which time alone can procure, I would not rashly abandon them to take up an abode in the wilderness, deprived at any rate for a length of time, of all those pleasures which long settled countries alone can afford. There is a genuine satisfaction too, in the breast of the true lover of rural life in causing fertility by his skill and industry, in place of sterility which the man cannot feel who works among stumps and fallen trees.

I promised to give you an account of my cotton crop grown on my manured land this year, provided it was worth recurring to. I will conclude the communication by doing so. Notwithstanding the season has been quite unfavorable for our cotton crops in this part of the country, its product will be quite fair. It is not all yet picked out, but enough has been gathered to convince me that it will make at least twelve

hundred pounds of seed cotton to the acre. There is no land to clear on this plantation, nor are there many uncleared acres in the county in which I reside capable of such a product. Had I wished to clear land, I could not have taken in more than thirty-five or forty acres with the force we employ, and have given to the other departments their proper share of attention: I manured about thirty acres this year. So I have almost accomplished already what I once looked upon as absurd, and I am not yet a master in the art of making manure. When land is to be cleared, it is necessary to employ the whole active force at command, not so in the making of manure. The labor generally necessary is scarcely missed—it glides on so smoothly when it is made a separate and distinct business, and one worthy of attention." W. A. G.

(From the New England Farmer.)

MANURE FOR GRASS LAND, TOP DRESSING.

It is wrong to attempt to take many crops of hay from any piece of upland without affording it manure: and although, as a general rule, it is best to break up, and take arable crops from land when it is manured there are important exceptions to this rule. Mowing land may be too wet, or otherwise unfit for the plough; and though much manure is wasted, when applied to grass land by its washing away by rains, and giving its fertilizing gases to the atmosphere instead of the plants it was intended to nourish, still there may exist cases in which its application to the surface of grass lands may be advisable. Mowing land in such cases, should, once in two or three years, have a top dressing of some manure suitable to the soil. Gypsum or lime well pulverized will be well applied to clover growing on a dry soil. "Gypsum," says the Farmer's Guide, "generally benefits all broad leaved plants, such as corn, potatoes, and most of the grasses. It is also good for young fruit trees. On grasses the best time to sow it, is when vegetation starts in the spring, at the rate of one bushel per acre, and the same quantity immediately after haying. Plaster has no effect on moist lands, and it has been thought not to be beneficial near the sea, but from some experiments, it appears that its operation depends more on the nature of the soil than its nearness to the sea coast."

Dr. Deane observed "If the application of top dressings to mowing ground were generally practised, and repeated as it ought to be, instead of the general, or rather universal neglect of it, it would put a new face upon things. A vast plenty of hay, double crops, two cuttings in a year, and much increase of wealth to farmers in general would be the happy consequences." Sir John Sinclair, recommends top dressing a growing crop, when it is suspected that the land is not rich enough to bring a full crop to perfection, and directs that this should be done as early in the spring as the land becomes sufficiently dry to bear the treading of a horse without poaching; and after the manure has been applied, the land should generally be harrowed or rolled. Soot, ashes, and other light manures are thus most advantageously disposed of.

Loudon says, "The roots of perennial grasses, whether fibrous or creeping, never strike deep into the soil, and thus deriving their nourishment chiefly from the surface, top dressings of well rotted manure, repeated on the same field for centuries, form at last a thin black stratum among the roots of the grass, which produces the most luxuriant crops."

Most agricultural writers as before intimated condemn the use of barn yard, stable or putrescent manure on grass land, because it is apt to be washed away, or to become dried matter of little value by exposure to the sun and air. Undoubtedly manure of this kind will, generally, prove more serviceable when ploughed into the ground and used for corn, potatoes, &c. but in many cases it is not bad husbandry to use the strongest sorts of dung as top dressings for

grasses. An English agricultural writer, whose works are well esteemed, says, "There is scarcely any sort of manure that will not be useful when laid on the surface of grass grounds; but, in general, those of the more rich dung kinds are most suitable for the older sort of sward lands; and dung, in composition with fresh vegetable and earthy substances, is more useful to the new lays, or grass lands. In Middlesex it is the practice of the best farmers to prefer the richest dung they can procure, and seldom to mix it with any sort of earthy material, as they find it to answer best in regard to the quantity of produce, which is the principal object in view; the cultivators depending chiefly for the sale of their hay on the London markets. It is the practice to turn over the dung that is brought from London in a tolerable state of rottenness, so as to be in a middling state of fineness, when put upon the land. It is necessary, however, that it should be in a more rotten and reduced state when used in the spring than when the autumn is chosen for its application."—*Dickson's Practical Agriculture*.

With regard to the season at which manure should be applied to mowing ground, a great difference of opinion prevails among farmers both in Europe and America. Loudon says, "In the county of Middlesex, where almost all the grass lands are preserved for hay, the manure is invariably laid on in October, while the land is sufficiently dry to bear the driving of loaded carts, and when the heat of the day is so moderated as not to exhale the volatile parts of the mass. Others prefer applying it immediately after hay time from about the middle of July to the end of August, which is said to be the "good old time," and if that season be inconvenient, at any time from the beginning of February to the beginning of April.

The Farmer's Manual directs to dress [in March] with stable compost, hog-pen, or such other well rotted manure as you have, such grass grounds as you have neglected in autumn; three loads now may be equal to two then; but it is best to secure a good crop even now. Your winter grain should now be dressed with plaster, if it was neglected at seed time; your mowing grounds, which are on a dry soil will pay you well for a bushel or two of plaster, or a few bushels of lime or leached ashes to the acre. A mixture of lime and ashes, plaster and ashes, or of all those ingredients has also been recommended.

Previous to manuring your grass land it will be well to harrow or scarify it. Rolling has been recommended to smoothe and consolidate the surface of grass ground, prevent the formation of ant-hills and render the effects of drought less pernicious. But scarifying or tearing the surface with a harrow is better, as it opens the ground to admit manure to the roots of the grass; and thus the force of the objections to the application of putrescent manure on grass ground is in some degree obviated. After this process it is often advisable to sow grass seeds to produce a new set of plants and supersede the necessity of breaking up the soil to prevent its being "bound out," as the phrase is.

(From the Genesee Farmer.)

HOW TO CHEAT THE MOON.

Some farmers are very careful to sow their spring crops and gardens at a proper time of the moon, and thus frequently anticipate or pass over the best season of the year. By attending to the following directions, they will escape all the inconvenience arising from the influence of the moon.

Select some fair day, as near the usual time of sowing as possible—arise very early in the morning, and sow your seed boldly. Cover all up carefully before night, making the land appear smooth and even. When the moon comes on the next evening, she will not be able to determine whether the field has been sown or not, and will therefore bestow no influence upon it, either bad or good.

It is important that the land be thoroughly dried, so that it can be made to appear natural.

Whenever wheat turns to chess, it is done by the influence of the moon. By attending to the above directions, and sowing clean seed, that evil may also be avoided. P.

HORTICULTURE.

CULTURE OF THE VINE.

MR. SMITH: *Baltimore, March 20, 1833.*

For some years past my attention has been drawn to the cultivation of the vine, as the means of giving to our country a new agricultural product, which, supplying the farmer with a wholesome beverage, and adding to his resources, may take the place of whiskey with the generations that are to come.

I have reluctantly convinced myself, that we shall never be able to produce from our native vines, in this latitude, a wine that will be fit to drink—and indeed, I may say that it has never been my lot to taste a sample of wine from our grapes, which could give place for hope. On the other hand the severity of our climate, during the winter and spring months, proves fatal to almost all imported varieties. I have sought, therefore, with great earnestness, for a foreign vine which combines the hardihood of some of the Rhenish vines, with those qualities which are necessary for the vat. That *desideratum* has, I think, at length been found in the Herbeumont Madeira or Warrenton grape. In No. 50, vol. xiv, of the *American Farmer*, Mr. Thomas McCall, of Georgia, has traced it satisfactorily to a foreign origin, and it indeed possesses many of the qualities of the best foreign wine grapes I have ever seen. It is an abundant bearer, the bunches are generally perfect, and if left to become quite ripe it is not unlike in flavor and appearance, the Miller's Burgundy.

In the spring of 1831, I received from Mr. Herbeumont five hundred roots, very well put up and in the finest condition. I had them carefully planted at eight feet apart one way and six the other, and pruned to two buds each. The growth of the vines was very luxuriant and beautiful. Nothing more was done but to keep them free from weeds and tie up the leading shoots. The wood ripened well, and no further attention was paid to them until March, 1832, when they were again pruned to three or five buds each. Two only had died; and these were indifferent plants through the summer. I consider this a sufficient proof that they will stand our winters, for that of 1832 was severe.

They were again pruned about ten days since; I have carefully examined them, and perceive throughout that perfect *compe*, which to a French vigneron is a sure indication of health and promise.

I have reason to believe, that I shall be able this fall to make some barrels of wine as an experiment. Z.

VEGETABLE PHYSIOLOGY.

TO CHECK THE GROWTH OF FRUIT TREES AND PROMOTE THEIR FRUITFULNESS.

MR. EDITOR: You inquire, "what will check the too free growth of fruit trees, so as to produce fruit buds, flowers and fruit? and if separating a part of the roots from the stock would produce the effect?"

These are important inquiries, and I will try to answer them, my own experience having fully illustrated the example stated, and its remedy.

In order to a full understanding of the subject, we must inquire:

1. Into the cause producing the effect, viz: the too rapid growth of the wood, and its consequent unfruitfulness; and

2. The legitimate and physiological treatment necessary to obtain the desired result.

Trees, and in fact all vegetables, have, like animals, three distinct periods of existence, viz: youth, maturity and decay. Youth may be termed that period in which the tree is growing to a bearing state, the time consumed for which depends much on its treatment and kind. Maturity is the term in which it yields its fruit; and decay, finally, but almost imperceptibly, follows sooner or later, and at last puts an end to its existence.

These three states, or periods, may be measurably retarded, or accelerated, by artificial causes. The young sapling, healthy and fresh from the nursery, planted into a kindly soil, and cultivated with attention, throws out and expands its vigorous shoots for many years. It finally, although it may seem a protracted time, arrives at its bearing age, and yields its annual supply of fruit, bountiful in proportion to its stature, and through a succession of years proportioned to its former term of youthfulness; and even age, as come it finally must, seems hardly willing to arrest its bounty, and lingers with tardy pace ere its withering hand is laid upon it. This I conceive to be the most natural and profitable course of all fruit bearing trees. I know that many people are in great haste to have their fruit trees yield their long expected reward, and in constant expectation of receiving it, have cultivated and treated them with much care. They are, to be sure, highly gratified in their exuberant growth, and if in a few years they do not yield a corresponding supply of fruit, are often apt to complain.

Now, on the true principles of vegetable physiology, the complainers are erring, and the tree right. They, for the purpose of getting fruit soon, stuff the tree with vegetable nutriment almost to repletion. The tree, in its turn, understanding well its own proper functions, thrives apace, intending at a proper time, to pay principal and interest for the kindness thus heaped upon it, and which it assuredly will do if suffered. But the owner is impatient for his fruit, and prunes and nurses the tree, wondering why it does not yield him fruit, and perhaps even threatens to destroy it for its perverseness. The simple fact is, the tree is not ready. It has not arrived at maturity, and is prevented from yielding fruit from the very nourishment and fulness continually received from the hand of its cultivator.

This I assume to be the natural state of the tree. But the object, as I infer from the questions at the head of this article, is, to obtain the fruit before the tree arrives at maturity, or, more technically, to force it.

The question now recurs, will you remedy it by cutting off a part of the roots?

By no means. The tree has no more roots than are necessary for its support, and would be much injured by parting with a share of them. Besides, I am unable to account, on physiological principles, how the cutting off a part of its roots will throw fruit buds into the top of the tree. The production of flowers and fruit require as liberal supplies of sap as that of wood, and if the source of supply be cut off, viz: the root, from whence is the supply to come?

But I proceed to consider the second inquiry, to wit: "to check the exuberant growth of wood, and cause it to produce fruit buds, flowers and fruit."

I shall assume that the trees are of well known kinds, and whose bearing qualities have been tested, and that they are situated in an open and well cultivated ground, as I believe the *whole* complaint can be made under no other circumstances. The trees have also been well pruned, and are accommodated with a good shaped head for bearing, and of fair size. My answer is: *Lay your ground, on which your trees stand, well down to grass, and let it remain so for several years.* The next year after seeding the ground, the growth of young wood will be much diminished, and fruit buds will form in moderate quantities; flowers and fruit will follow the next season. That year, if the tree be an annual bearer, an increased number

of fruit buds will be found, and so continue in annual succession. If, after a few years, the tree is too stationary in its growth, for it certainly will not throw out young wood very rapidly, plough, and cultivate, and manure the land, and you can supply the trees with any amount of young wood required, although the bearing will still continue in an abated degree. If you find your trees get too thrifty, you have only to seed down again, and manage as circumstances may require.

That this method has been tried with success I know, for I did it myself some years ago, and am indebted partly to accident for the discovery. About the year 1817, my father had an orchard which, when planted, nearly surrounded his garden, and which was used mostly for mowing ground. The trees were young, perhaps fifteen years old, and had grown tolerably well. A few years before the time I speak of, the garden had been enlarged on two sides, which took, on each side a row of apple trees within the fence. The land being well cultivated, the trees grew astonishingly; and not being pruned, acquired immense heads, and bore little or no fruit, while those in the meadow, although of much less size, bore abundantly. I was then a boy of eighteen years old, and the trees were delivered over to my care, "to prune into good order." I had read "Perry's on Fruit Trees," and supposed I knew all about it; so at it I went, with the ax and saw, and took out full one-third of their tops, supposing that they would now go to bearing at once. But not so. They grew as before, and bore a little better than they had done. I confess I knew not what to do, although, if I had let them alone, they would have borne, when "their time come," all the better for it; yet I was impatient for their fruit. At length the plan suggested itself to seed down the ground where they stood to grass. It was done, and in a short time the growth was nearly stopped, and they bore abundantly of the finest apples.

They are now, for I saw them two years since, much the finest of all the trees in the orchard, from the benefit of having a rapid growth in their youth; and the others, from growing less rapidly when young, and bearing so much sooner, have a much older appearance, and were the ground in which they stand not occasionally ploughed and cultivated, would soon bear evident marks of decay.

This matter now must be accounted for on rational principles, and it may truly be hard to compel a person to say what makes the tree bear wood one year and fruit the next, when the whole process is hidden in the earth, and a profound secret of nature. I will, however, state my own opinion, and others may judge of its correctness.

While trees are young, their roots expand and run near the surface of the earth. If the ground be cultivated, the earth is warm and light, and the roots absorb much nourishment, and a rapid growth of young wood is the sole consequence. In process of time, as the tree increases in size, the roots find their way deep into the earth, where the temperature is lower, and its growth is by degrees checked; fruit buds are consequently formed, and the tree comes into the bearing state. Now, putting land into grass has the same effect. The sun is hidden from the earth. The temperature is lower—the richer nutritious gases of the soil are absorbed by the grass, and the same result is produced as if nature's age had forced the roots more deeply in the ground. ULMUS.

(From the Genesee Farmer.)

MEMORANDA IN VEGETABLE PHYSIOLOGY.

PLANTING.

Extract.—"The pith forms the central circle of a root, stem or branch. It is a cellular membranous body of a silvery white color. As the tree or root advances in age, and the timber is perfected, the pith gradually loses its original spongy texture, the cells of which it is composed becoming more and more compressed, until all appearance of it is lost in the wood, excepting that the concentric circle which it occupies appear whiter than the other annual layers. But although the pith thus disappears in the old, it still continues in progress with the young wood of the root, stem or branches; and the periodical fibres or radicles of the former, and the buds or embryo branches of the latter, will on examination be found to originate from it. When a branch is pruned off close to a stem, wherein, from age the pith has disappeared for some distance above and altogether from below the origin of the amputated branch, *no reproduction of shoots takes place, in whatever season the pruning may be performed*, but should a portion of the branch be left to the stem, from *that* buds and shoots will spring. It also happens, that when a branch is pruned off close to a young healthy stem, containing perfect and active pith, before or shortly after the completion of the midsummer growth, which usually takes place before the end of July, *no production of shoots follows the operation*, but the effort of the vital functions of the plant appear to be wholly directed to *cover the wound with fresh bark*. Should the pruning however be performed in spring, before or shortly after the expansion of the leaves, or after their fall in autumn, *a reproduction of buds and shoots ensues*, and a slower progress in the formation of new bark is apparent." *Useful and Ornamental Planting*, p. 4.

Remark.—In this extract we have an illustration of the application of science to practice. It teaches:

1. That the pith is necessary to the production of buds and radicles (fibrous roots,) and that these are both annual.
2. That when a branch is taken off close to the bole or body of a tree, no reproduction of shoots takes place; but that shoots will spring from the spurs or stumps of limbs. This indicates the propriety of cutting always close to the bole.
3. That midsummer pruning, when the sap is for some days or weeks comparatively quiescent, is the most effectual in preventing the growth of new shoots, and in speedily covering the wounds with new bark; and that the reverse of this happens when trees are pruned in spring, autumn or winter.

It cannot but have been remarked, that orchards pruned in spring or fall, especially if the labor has been omitted some years, or performed in a careless manner, become unsightly and unproductive, from the innumerable sprouts or shoots which succeed the operation. I have two successive years pruned my orchards in July, after the grass or grain growing in them was cut, and have reason to be highly gratified with my innovation upon the old practice. Very few shoots were subsequently produced, and the wounds were nearly covered by new bark before autumn. The operation of pruning, to be well done, should be performed annually, or at farthest biennially, when the knife will be the principal instrument required, and the wounds so small as to heal readily.

Extract.—"The presence of leaves is essential to the growth of buds and branches, and consequently to that of the pith in these and in the roots; but the leaves are not otherwise necessary to the formation and growth of the *fibres or radicles of the root*, as these are produced in abundance when the plant or tree is leafless, and even during winter, when the ground is covered with frost and snow, the reservoir of nourishment in the *pith* being probably sufficient for that purpose."

Remark.—"The food is elaborated in the leaves,

while these organs perform their functions, descends through the inner bark, and a portion of it is communicated to the pith by the medullary rays. Thus the plant continues to be fed, if the term is admissible, by the prepared food, until the new leaves are expanded in the spring, and exercise their functions. The practical use I should make of this fact would be to transplant in autumn, and as soon as the leaves have finished their office, while the plant abounds in elaborated food, in order that this may produce new radicles (months) for the early supply of food in the spring. Prof. Lindley, than whom I can quote no better authority, decidedly concurs in giving the preference to fall planting. B.

(From the Genesee Farmer.)

VEGETABLE NUTRITION.

According to a table constructed by Sir H. Davy, from experiments made to ascertain the proportions of nutritive matter contained in different vegetables, the different varieties of beets contain from 136 to 151 parts in every 1000, parsnips 99, carrots 98, and turnips 42. As it is now ascertained that a greater quantity by weight of mangold wurzel can be raised upon a given quantity of land than either of the roots mentioned, it follows that, if they do not require a greater expense in cultivation and preservation than the others, their cultivation will be attended with the greatest profit. It is stated, by those who have had experience in the cultivation of mangold wurzel, that a crop can be raised with the same labor that is necessary for a crop of potatoes; and that they can be preserved in cellars, or elsewhere, by keeping them from frost through the winter, and that they will retain their nutritive qualities through the succeeding summer. Although we are opposed to a general innovation in agricultural pursuits, yet we recommend a fair trial of the cultivation of mangold wurzel, for the benefit of stock farmers. It is desirable to find out the cheapest article with which farmers can supply their stocks with green or succulent food during our most severe winter weather. Cabbage and turnips are liable to be destroyed by insects, which renders those crops too uncertain. Carrots and parsnips require much labor. Potatoes require boiling, but all things considered, are at present our most valuable crop for the above purpose in general cultivation, so that experiments should determine between them and mangold wurzel.

RURAL ECONOMY.

(From the Village Record.)

CHESTER COUNTY (PA.) CATTLE.

The cattle mentioned in the last RECORD, were exhibited at WM. REED'S HOTEL, from Tuesday morning until Thursday at noon. They were very handsome, and called together hundreds of visitors who were favored with excellent sleighing, and the weather being pleasant the inducement to such visit and view, was increased. At about two o'clock, on Thursday, the two heaviest oxen, those fed by Emmor Seeds, on Brandywine Farm No. 4, were placed on two connected cars, at the depot of the West-Chester Rail Road—and being properly secured—two horses were harnessed thereto—and they left the depot, cheered by three loud huzzas in the presence of not less than three to five hundred persons. The purchaser, Mr. HENRY BONAFER, we understand to be an enterprising and liberal victualler of Philadelphia. For this pair of oxen, he offered and we presume paid \$325 00 to E. Seeds, to whom he gave the privilege of receiving that sum or \$11. 00 per cwt. It excited a degree of hilarity in the spectators, to see the cheerful countenances of the farmers, and to hear their jokes, while viewing the just proportioned and well-fatted animals which were about to leave the

TEA.—Most ladies consider it sufficient that the tea kettle has boiled, and not that the water be always boiling hot when it is poured into the tea pot. To make a good dish of tea, scald the tea pot, put in the tea, pour on two or three table spoonfuls of water; let it stand a few seconds, and then fill up with the water *boiling* hot every time the tea pot is filled; the kettle should be previously put on the fire.

country to gratify the palates of the citizens.—See below the Report of the committee of Farmers and Graziers.

At a public meeting of farmers and graziers, held at the house of WILLIAM REED, in the borough of West-Chester, on Tuesday the 5th of March, 1833, DAVID WOELPPER was called to the chair, and Jesse Pusey appointed secretary.

The object of the meeting being stated to be, to consider the propriety of taking some order in relation to a number of cattle which had been brought to the borough for exhibition: on motion it was Resolved, That Jesse Pusey, Joel Pennock, Edward Inskip, Samuel Morris, Jr., and John Hickman, be a committee to examine the said cattle, exhibit them to the company assembled, and make report to the meeting.

The meeting then took a recess for two hours, and afterwards met again in the same place, when the above mentioned committee submitted the following report, which was unanimously adopted:

REPORT.

The duty assigned us by the appointment of the meeting has been performed. At 5 o'clock, P. M. five remarkably fine looking cattle were driven up under our direction in front of the hotel, and exhibited to a large number of our fellow citizens. Of those cattle, two were fed by Emmor Seeds, of East Bradford, two by John Gheen of Pennsbury, and one by John Hickman, of West Bradford. Those belonging to the first named gentleman, were the largest and heaviest, and probably exceed in weight any cattle heretofore fed in the county. Those of Mr. Gheen are exceedingly fine, and we are persuaded have seldom been surpassed in neatness and fatness by any of equal age. The heifer of Mr. Hickman, is young, plump and beautiful in its proportions, and appears as well fed as any of the lot.

The estimates of the weight of these cattle are various, and the different members of the committee find some difficulty in forming an unanimous judgment; but have little hesitation in believing that those of Mr. Seeds, will weigh from 3000, to 3300 lbs. and Mr. Gheen's from 2100 to 2300 lbs.

This exhibition has afforded much satisfaction to the committee, and they consider the effort to excel in the feeding of cattle, very creditable to the gentlemen concerned. Their example we hope will be imitated and their success emulated by others. The credit of the county as a grazing and feeding district, will be elevated by the attempt and we shall all find our interests promoted and our feelings of pride gratified by the result.

On motion, Resolved, That the proceedings of this meeting, together with the report of the committee, be published in the papers of the county.

DAVID WOELPPER, Chairman.

JESSE PUSEY, Secretary.

The cattle referred to in the foregoing proceedings have been purchased by that enterprising citizen Mr. Henry Bornell, and are destined as we understand, for the Philadelphia market.

(From the Genesee Farmer.)

THE HONEY BEE.

ITS CULTIVATION UPON THE HOUSING PLAN.

Hammond's Port, Feb. 1, 1833.

I have read the communication of ULMUS, [published in the American Farmer, Vol. XIV. No. 46,] on the cultivation of the bee, with much interest. Like him, I am a new beginner in the rearing of this useful little insect. Having read a communication two years since of Judge BURL, in which the housing system is recommended, I determined to make the experiment. But, like Ulmus, I was not sufficiently informed in the particulars relative to this mode of culture, the placing of the hive, the arrangement of the interior of the house, &c. For this I had no other guide than my own judgment. Last winter I pre-

pared a room in my shed loft—obtained a hive of bees, and placed them in it. Thus far I am much pleased with the result of the experiment. The room is about five feet by six on the east end of my shed, and facing the garden, ceiled and made tight to exclude insects and secure against cold in the winter. I placed the hive on a shelf against the side of the house next the garden, and even with the shelf made a hole, for the egress of the bees, four inches wide, and one and a half inch deep, in which I inserted a spout on the outside of the house ten inches long, with an orifice two inches wide, and one-third of an inch deep. This was the more effectually to prevent the entering of the bee moth. Besides this, I inserted two others, to be closed until the bees increased so as to need them. Even with the top of the hive I formed a rack of narrow strips of lath, supported by cross pieces, far enough apart for the bees to pass between them. Above this I placed two more tiers of lath, about sixteen inches between the tiers, with rods passing between the tiers to support the combs. The house was made perfectly dark, with a small tight door opposite the shelf for occasional entrance. The bees commenced operations vigorously in the spring—cleared the hive of dead bees, &c. filled up the vacant cells; and began to form their combs on the outside of the hive, attaching them to the strips of lath. To my extreme regret, the worm soon made its appearance, so early that I was convinced it was in the hive when I obtained it, or the eggs from which it was produced. The worms increased considerably—went through their several changes, and abundance of the miller came forth. The bees, however, kept on working, though several of the combs were injured by the worms, and formed thirty or forty weight of beautiful white honey outside of the hive. On the approach of cold weather, the bees all collected into the hive, and left the outside combs free, which were removed with perfect ease. Had there been no worms in the hive when I obtained it, or eggs of the moth, I doubt whether the apiary would have been much molested by them, as I several times watched the motions of the miller in the evening outside, and never saw but one enter. I am now making several alterations in my house, which I think of importance.

1. *To make the house warmer.* For this I shall make the floor double, and perfectly tight; the walls also double and filled in with straw or chaff—perhaps dry tan bark would be better; and in addition to this, plaster the room inside, that there may be the fewest possible cracks or joints for the moth to deposit her eggs, and for the entrance of the cold air. I am satisfied the bees in my room would have perished with the cold, if they could not have found place in the hive.

2. *To simplify and improve the internal arrangement.* To this end, I shall suspend the hive by wires, agreeable to the suggestion of Ulmus, near the top of the room, without any bottom board to it, that the worms, if there be any in it, may fall down, and be unable afterwards to effect a lodgment in it. And instead of the strips of lath, I shall substitute shelves, about eighteen inches wide, smooth on the upper side, with holes bored through them for the bees to pass up and down; the shelves to rest on cleats at the ends, but not to touch the side of the wall, leaving sufficient room for the bees to pass, and forming no hiding place for the worm, or deposit for the eggs of the moth; the joints at the ends of the shelves to be carefully filled with putty, or some other substance; two rods must run between these shelves, as in the other construction, lengthwise, supported by standards. These shelves will be preferable to the racks of lath, on account of their affording fewer crevices, and the greater ease with which the combs may be taken from them.

3. *To ventilate the room.* This, I think, will add to the health of the bees, by making their room cooler in summer, carrying off the perspiration, and secure

against the combs breaking down by too great heat, as was the case with mine in the fore part of the summer. To effect this, I shall make two holes through the floor, covered both outside and inside with a fine wire screen, having on the outside a slide to stop it as cold weather approaches; and in the upper ceiling, one or more tubes are to be inserted, communicating with the outside, to be covered with a wire screen, and having slides to stop them on the outside in the winter. By making their house thus tight and warm, and putting up sufficient fixtures, I see no reason why the bees may not increase till they fill it. To give them room to work for many years, I shall put a range of shelves on the south as well as on the east side. I shall be particularly careful to make every joint perfectly tight wherever the bee moth may deposit its eggs. By taking this precaution, and using these long tubes or spouts for the entrance of the bees, I think the worm may be kept out. These are the alterations which I am now making in my apiary. Time will test whether they are improvements or not. In another communication I shall suggest what I consider an improvement upon the plan of Ulmus, in the construction of his extended hive.

(From the Southern Planter.)

RAISING CALVES BY HAND.

Traverseville, Feb. 12, 1833.

MR. EDITOR.—Having found you very desirous of communications connected with agricultural concerns, I have thought proper to recite to you my method of raising calves by hand, and thereby not only enlarging the dairy product, but actually rearing a finer animal and in less time. At one day old, the calf is removed entirely from the dam, and fed at first with milk fresh from the cow and in a pail in which the feeder may lay his hand, putting a finger into the calf's mouth by which the little animal will soon drain the pail. By a little care and ingenuity in the feeder, the calf will presently either drink the milk, or thrusting its nose to the bottom of the pail, suck up the contents every drop. Having taught the creature to take its food in this artificial manner, proceed to add to portions of thin corn meal mush, as much skimmed milk as will reduce the mush to a proper consistency for suction, and render the mixture a full feed for the calf. Feed thus three times a day. Any child eight years old will take interest in administering to the little beast, and be fully competent to discharge the office of feeder for a number of calves.

Should the diet ever disagree with the calf, substitute fresh milk a time or two, and all will be well again. Probatum est. Yours, respectfully,

GEO. P. COOPER.

(From the Genesee Farmer.)

DISEASE IN CALVES.

Corington, Feb. 12, 1833.

MR. EDITOR.—In the fall of 1831, I lost three calves by a disorder altogether new to me. They were taken lame at first in one of the hind legs, and generally died in about from 24 to 48 hours after. On opening them, the hind quarter above the gambrel joint appeared mortified and rotten. In some the intestines appeared affected in the same way. The blood before death appeared thin and watery. Last fall I lost two more, with the same disorder I believe. These, however, appeared affected throughout the system. These calves were all in good order. My neighbors have lost several with the same disorder, and I have not found any one that can give any light on the subject. The object of this communication therefore is, to see if you, or any of your correspondents, can give us any information on the above subject; for unless something can be done to prevent or cure the above disorder, the raising of calves will be rather unprofitable business in this town.

A SUBSCRIBER.

Prices Current in New York, March 23.

LANCASHIRE GOOSEBERRY PLANTS.

Just received from England the following choice assortment of the celebrated Lancashire Gooseberry Plants, which are offered to the public with confidence in their superior quality, their genuineness, and fine condition. They will be packed so as to be carried safely any distance; but those that have to go far would better be ordered without delay. The following is a list of twenty-seven kinds:

WHITE FRUIT—Capper's Bonny Lass, Boardman's Smiling Beauty, Holden's White Muslim, Saumpson's Queen Ann, Yates' Thrasher, Leigh's Toper.

YELLOW OR AMBER—Nelson's Waves, Hill's Royal Sovereign, Weedham's Delight, Large Golden Queen, Forbes' Golden Eagle, Sandiford British Favorite.

RED—Walker's Bank of England, Kirsham's Fairmaid, Jolly Minor, Dean's Glory of England, Chadwick's Sportsman, Boardman's British Hero, Boardman's Prince Regent, Fletcher's Crown Regent, Millington's Crown Bob, Eckerly's Jolly Printer, Bell's Glorious, Bratherton's Overall.

GREEN—Hoppley's Shannon, Parkinson's Laurel, Allan's Glory of Ratchiff.

These plants have been carefully selected from the best sources by a competent person, and are truly fine.

Prices.—Several of these varieties are sold from the gardens at from 50 cents to \$1 per plant, (they are all superior kinds,) but I offer them as follows:

Purchasers may select at 40 cents each, or thirteen plants for \$5. When the selection is left to us we will send three plants for \$1, or sixteen for \$5. The number of each kind is very limited.

ANTWERP RASPBERRY AND CURRANT BUSHES;—GENUINE.

Just received a few plants of the Red Antwerp Raspberry, best kind, at 25 cents each, or \$2.50 per dozen. Common kind usually known by this name, and bearing fine fruit, 12½ cents each, \$1.25 per dozen, or \$9 per hundred.

Genuine Antwerp or Large Dutch Currants, 25 cents each, or \$2.50 per dozen.

Address J. I. HITCHCOCK.
American Farmer Office and Seed Store.

GRAPEVINES AND CUTTINGS.

For sale at the American Farmer Office and Seed Store, the following, which can be sent safely any distance:

ROOTED VINES.

Herbemont's Madeira, two years old, 83 cents each, \$3.50 per dozen, or \$25 per hundred.

Isabella, very fine roots, two years old, 37½ cts. each, or \$1.00 per dozen.

White Scuppernon, one year old, 25 cents each, or \$2.50 per dozen.

CUTTINGS.

Cunningham, finest native grape, both for wine and table, 12½ cents each, \$1.25 per dozen, or \$9 per hundred.

Woodson, very fine do. do. same price.

[For description of these, see American Farmer, Vol. xiv. No. 33.]

Norton's Virginia Seedling, fine, same price.

Cuttings of the Isabella, Muscadell, and Golden Chascelas, 50 cents per dozen. J. I. HITCHCOCK.

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals,—viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	200
Do 2 " " Do "	250
Do 1½ " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each.

Half Blood and upwards.—A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenth Durham Shorthorn, very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$100.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address J. I. HITCHCOCK.
Amer. Far. Office.

DOUGLAS' WHEAT MACHINE,

Made by Z. Booth, New York.

The Subscriber has the agency for vending this very superior implement, and has also a sample of a two and four horse power machine, which he will exhibit at his warehouse, Camden street, and also testimonials of the highest respectability, who have a practical knowledge of their worth.

HENRY W. GRAY.

March 29.—24

GRASS SEEDS FOR SALE.

Just received,

One hundred bushels Orchard Grass Seed.

One hundred and fifty bushels Herd's Grass Seed.

Sixty bushels Tall Meadow Oat Grass Seed.

Also on hand, prime Timothy and Lucerne Seed.

SINCLAIR & MOORE,

Mar. 29.

Corner of Pratt and Light streets.

SINCLAIR AND MOORE'S NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of Hardy Rose Bushes, (among which is the much admired Greville,) double Albazeas, Honeysuckles, Cornus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Alanthus, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets.

Feb. 22.

FIELD AND GARDEN SEEDS, &c.

J. S. EASTMAN offers the following Seeds for sale, viz. CLOVER, TIMOTHY, MEADOW OAT GRASS, MILLET, LUCERNE, COW PEAS, LARGE YELLOW PUMPKIN, and EARLY WHITE CORN.

Also a general assortment of GARDEN SEEDS, and WHITE ONION SETS.

Likewise in store, a general assortment of AGRICULTURAL IMPLEMENTS, embracing almost every article in the farming line, which he will sell low for cash or approved city acceptances.

He must decline opening any new accounts, except with those who will be liberal customers, and can give good references; and all such accounts he expects to be promptly settled once a year; and those who have accounts standing on his books over one year, are desired to settle the same. All Grass Seeds must be considered cash. Liberal discounts will be made on all implements purchased by merchants and others to sell again.

Feb. 15.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—A little improvement has taken place in the produce business. Howard street flour from wagons commands readily \$5.25, and considerable sales have been made from stores at our quotations. Millers are asking \$5.50 for city mills flour, though we do not hear of any sales at that price. Wheat has improved considerably, and our quotations of red may be considered its fair price.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop. common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 26.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 42 hds. Md.; 30 lds. Ken.; and 1 hhd. Ohio—total 73 hds.

FLOUR—best white wheat family, \$6.75 a 7.25; super Howard-street, — a 5.50; city mills, 5.44 a —; city mills extra 5.50 a —; Corn Meal, bbl 3.50; —; GRAIN, best red wheat, 1.10 a 1.15; white do — a —; —Corn, white, 60 a 62, yellow, 61 a 63;—Rye, 65 a 68 —OATS, 37 a 40 —BEANS, 75 a 80 —Peas, 65 a 70 —CLOVER-SEED 8.00 a ——TIMOTHY, — a ——ORCHARD GRASS 3.00 a ——Tall Meadow Oat Grass 2.00 a 2.50 —Herd's, — a ——Lucerne — a 37½ lb. —BARKLEY, FINEST 1.50 a 1.62—COTTON, Va. 10 a 12—Lou. 12 a 13—Alab. 10 a 11½—Tenn. 10a. 12; N. GENERAL

Agricultural and Horticultural Establishment; COMBINING.

A Seed and Implement Store, a General Agricultural Agency, and the Office of the AMERICAN FARMER, at No. 16 South Calvert street, Baltimore; in connexion with a Stock and Experimental Farm, Garden and Nursery in the vicinity.

It is an extra number of the Farmer, containing a prospectus of the "Establishment," and a "Catalogue of Seeds," &c. kept for sale, shall be sent gratis to any person who shall by mail or otherwise furnish his address for that purpose.

AGENTS FOR THE FARMER.—All postmasters are requested to act as agents for the Farmer, and to require a strict compliance by subscribers with the terms, especially the third item. They are authorized to retain one dollar for each new subscriber, and ten per cent on all other collections. The list of special agents is published in the Farmer every third week. (Terms next week.)

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, APRIL 5, 1833.

MANGLE WURTZEL FOR CATTLE. Last year we made an experiment with mangel wurtzel for cattle, and the result was highly satisfactory—so much so that we shall hereafter adopt it in preference to all other root crops for the purpose. Having about the sixth of an acre of ground prepared for early corn for which we had not seed enough, we determined to plant it in mangle wurtzel as an experiment, having very little confidence in its equality with ruta biega. We accordingly soaked the seed twenty-four hours in warm water, laid off furrows about two feet apart, and dropped the seed six or eight inches apart, covering it as we do corn. When the plants were up, we passed over the field with a weeding hoe, and subsequently run a small plough through it twice, clearing out the weeds with a hoe. This is all the cultivation it had, and we feel certain that all the work bestowed upon it, including the original preparation of the ground for corn, did not amount to more than two full days work for one man. We put no manure on the ground, though it had been manured the year before for potatoes, and for planting in early York cabbages, which were killed by the severity of the winter. The soil was a fair medium mold, a mixture of sand, clay and vegetable matter; high ground, but level. When the mangel wurtzel was gathered, it was estimated by every one at seventy-five bushels; some more, but none less. It was also perfectly evident that we might have taken at least one-fourth more, if not double the quantity from the same ground, had we planted more carefully and laid the rows fifteen or eighteen inches apart, instead of two feet. There was many places in the rows where there was not a plant for six or eight feet; and then again many places where they were so crowded that the roots could not fairly develop themselves.

As food for cattle, especially for milch cows, our experiment was as follows: In October, our best milch cow began to fail in her milk, and we cut an arm full of the tops of the mangel wurtzel for her; this seemed to have a good effect, and it was repeated night and morning for a week, when she fully recovered her usual supply. The leaves were then withheld, and she immediately failed again in her milk. At that time her full quantity was about twelve quarts a day, and when the mangle wurtzel leaves were withheld, the quantity she gave was only about six quarts. She had a good pasture, with an excellent stream of water in it, and plenty of salt during the time; but at that season the grass does not afford sufficient nutritive matter.

After another week we began giving her the roots of the mangel wurtzel, cut small and occasionally sprinkled with shorts or corn meal, and a little salt, one peck of the roots given thus had the same effect on her milk that the tops had; and we suspended these a week, to try their effect the more certainly. The result was as above stated, a conviction that mangel wurtzel is the best and most profitable root we can raise for milch cows.

After cutting off the leaves, they very soon grow out again, so that they may be cut every fortnight. But we think it better to select the largest roots from crowded places, and give them tops and all; as we think the new growth of leaves is at the expense of the roots.

BUTTER.—A friend waited on us, yesterday, to communicate the result of a process, which had been recommended to him, of restoring butter to its original sweetness. Incredulous as he was, he made the experiment, and he authorises us to say it was entirely satisfactory. It consists simply of churning the butter with sweet fresh milk, in the proportion of about 3 lbs. of the former to half a gallon of the latter. Butter, thoroughly rancid, by this simple process, was rendered

sweet and good. Our citizens, in view of the present scarcity and dearthness of butter of even tolerable quality, will not fail to appreciate this discovery.

[Fredericksburg Arena.

THE HORTICULTURAL SOCIETY OF MARYLAND.

For the diffusion of Horticultural Science and the Improvement of the Art of Gardening; Associated Nov. 20th—Incorporated by act of the legislature, at December session, 1832.

The Council of this Association have resolved to open the public proceedings of the society, by an exhibition of plants, flowers, fruits and other vegetable productions.

The exhibition will be opened on the eleventh day of June next and will continue during that and the following day.

On the eleventh of June, popular lectures will be given in the hall of exhibition, and on the twelfth, the society will hold a public meeting, when an address will be delivered.

In furtherance of the views of the society, the Council have resolved to offer premiums to the aggregate amount of ONE HUNDRED DOLLARS, to be awarded to the finest objects exhibited, by a committee of judges appointed for that purpose.

The following gentlemen have been appointed to act as a committee of arrangement, viz: H. F. Dickelut, chairman, Z. Waters, Geo. Fitzhugh, James Moore, Edward Kurtz, I. I. Hitchcock, Sam. Feast, John Feast.

All who feel interested in the advancement of Horticulture, are invited to lend their aid in furtherance of this design. Those wishing to exhibit plants or other objects of Horticultural interest, will please communicate their views to the committee of arrangement, stating at the same time the articles they design to exhibit.

Letters on the subject, must be addressed to the chairman of the committee, from whom any further information may be obtained.

Baltimore, April 5, 1833.

(From Silliman's Journal.)

ON THE CUTTING OF STEEL BY SOFT IRON.

Extract of a letter to the Editor, from the Rev. Herman Daggett.

"I take the liberty to communicate to you a fact, which has lately come to my knowledge, and which I judge may be of considerable use to the mechanics, and perhaps in philosophy. It may not, however, be new to you.

"Mr. Barnes, (a cabinet maker of this place) had occasion to repair a cross cut saw, a saw to be used by two persons, of a very hard plate, which would require considerable labor in the usual way of filing. He recollected having heard that the Shakers sometimes made use of what he called a buzz to cut iron. He therefore made a circular plate of sheet iron, (a piece of stove pipe) fixed an axis to it, and put in his lathe, which gave it a very powerful rotary motion. While in motion, he applied to it a common file, to make it perfectly round and smoother; but the file was cut in two by it, while it received itself no impression. He then applied a piece of rock crystal, which had the desired effect. He then brought under it the saw plate, which in a few minutes was neatly and completely cut through longitudinally. When he stopped the buzz, he found it had received no wear from the operation, and that he could immediately apply his fingers to it, without perceiving much sensible heat. During the operation, there appeared a band of intense fire round the buzz, continually emitting sparks with great violence. He afterwards marked the saw for teeth, and in a short time cut them out by the same means. It seemed evident that the buzz in effecting the division, never came in actual contact with the plate."

(From Proceedings of the N. Y. State Agricul. Society.)

NEW YORK STATE AGRICULTURAL SOCIETY.

REPORT ON AN AGRICULTURAL SCHOOL.

(Concluded from page 17.)

Your committee have thus complied with the requisitions of the society, in submitting the plan of an Agricultural School, and an estimate of the expense necessary to establish and put the same into successful and permanent operation. It only remains for them to state their opinion of its utility.

The agriculture of a country affords the best criterion of its prosperity. Whether we compare kingdoms, states, counties, districts or farms, the condition of this branch of labor, which they severally exhibit, is a sure index, not only of the pecuniary, but of its moral condition. It is no less an axiom founded in truth, that agriculture prospers or languishes, in proportion to the science and skill of the men who manage its labors. It is not the natural fertility of the soil, so much as the intelligence and industry of those who till it, which gives to husbandry its interests and its rewards. The man who devotes the energies of a highly cultivated mind, to the improvement of this primitive and all important branch of labor, is a public benefactor. Cincinnatus did more to immortalize his name, and to command our applause, by his love of rural labors, than by his military exploits. Washington, amid all the honors that irradiated his brow, sought his highest pleasures in the business and retirement of the farm. And it was the first remark of our present chief magistrate, to the writer, after introduction, that he would not forego the pleasures of the farm for all the honors and emoluments that this nation could confer upon him. Education enables man to appreciate the wonderful provisions which God has made for his happiness in rural life, and imparts to him the ability of diffusing instruction and happiness to multitudes around him.

It should be the policy of government, therefore, which watches over the interest of all, to infuse into the labors of husbandry, all the lights of science and knowledge—to take care to expand and elevate the minds of those who are to give it efficiency and character, and to call forth skill and industry by proffered rewards. With us these considerations possess peculiar force. Our population and business are emphatically agricultural, and every aid which is extended to this class, benefits, indirectly, every portion of the community. Agriculture constitutes the fountains of the thousand rills which, swelling and traversing every part of the state, propel the spindle and the hammer of the artisan and the manufacturer, and finally, by their union, make up the mighty stream of commerce which unceasingly flows into the Atlantic.

That our agriculture is susceptible of improvement—that the products of its labors may be doubled, nay quadrupled, must be apparent to those who have compared our husbandry with that of some European countries, or who have contrasted, at home, the well cultivated district, or farm, with those which are badly managed. How is the desired amelioration to be effected? How can a better husbandry be so well promoted, as by teaching it to our youth?—by sowing our seed in the spring time of life? Prejudice no where retains a stronger hold than among farmers who have approached or passed the meridian of life. While some retain old practices, for want of confidence in their knowledge to guide them in better ones; others lack the first requisites to improvement—a consciousness that their system is not the most useful; while not a few are influenced, in their hostility to public means of improvement, by the desire to keep things to their own level. If we would efficiently improve this great branch of business, and elevate its character, as well as the character of those who are engaged in its operations, we must do what universal experience has shown to be the only sure

method;—we must lay our foundation in the rising generation—we must teach the *young* idea how to shoot—we must instruct the head to help the hands. Our physical and mental powers are twin sisters. They lighten each other's labor, and mutually impart a zest to each other's enjoyments. And as it is becoming common to introduce manual labor into literary schools, it is courteous that literature and science should requite the civility, by associating with the inmates of schools of labor.

Agricultural schools, although of modern date, have nevertheless been established in most of the states of Europe, and their utility has been fully demonstrated. Who has not heard of the school of Fellenburgh, at Hoffwyl, or of Von Thayer, at Moegeln—to which young men are sent from every part of Europe, and even from America? In France and Prussia agricultural schools have been founded and maintained by the governments. If they are found to be beneficial, and worthy of governmental support, in countries where power is vested in the few, how much more salutary must they prove here—where our institutions receive the impress of their character from the many, and where the perpetuity of these institutions depends emphatically upon the intelligence and virtue of the agricultural population. Despotism will never flourish in the American soil, but through the ignorance, and we may say consequent depravity, of its cultivators.

Your committee recall to recollection, with feelings of pride, the munificent benefactions of the legislature, to advance the literary character of our state; and the fact, that comparatively nothing has been done, legislatively, to improve our agriculture, which employs five-sixths of our population, can only be ascribed to the fact, that nothing has been asked for—nothing thought of. Our public colleges and academies, for literary instruction, are numerous and respectable. They meet our eye in almost every village. But where are our public schools of labor? Where is the head taught to help the hands, in the business which *creates* wealth, and which is the grand source of individual and national prosperity and happiness? Our literary and professional schools have been reared up and sustained by the expenditure of more than two millions of dollars from the public treasury, and they continue to share liberally of the public bounty. It will not, however, be denied, that the benefits which they dispense are altogether partial,—that the rank and file of society, destined by heaven to become the conservators of civil liberty, are virtually denied a participation in the science and knowledge,—in the means of improvement and of happiness, which they are calculated to dispense. Is it not a mandate of duty, then, as well as of expediency, that the benefits of public instruction should be more generally dispensed? We hazard not the fear of contradiction in assuming, that if a moiety of the public moneys, which have been appropriated to literary schools, had been judiciously applied, in rendering science subservient to the arts, and in diffusing the higher branches among the laboring classes, the public benefits from the appropriation would have been far greater than they are at the present day. How many hundreds may now be pointed out, of liberal education, who are mere ciphers in society, for want of the *early habits of application and labor*, which it is the object of the proposed school to form and to infuse! And how many, for want of these habits, have been prematurely lost to their friends, and to a purpose of usefulness for which man seems wisely to have been created—that of doing good to his fellows.

From a full conviction, that the interests of the state not only warrant, but require, an appropriation of public moneys to this object, your committee beg leave to recommend to the consideration of the society the following resolution:

Resolved, That a respectful memorial be presented to the legislature, in behalf of this society, and of

the great interest which it represents, praying that suitable provision be made by law, for establishing a School of Agriculture, on the plan recommended in the preceding report; and that the co-operation, in this application, of societies and individuals, friendly to the object of the petition, be respectfully solicited.

(From the Albany Argus.)

STATE AGRICULTURAL SCHOOL.

It will be seen by a reference to the proceedings of the senate of yesterday, that Mr. SUDAM, from the select committee of eight, to which was referred the memorial of the State Agricultural Society, reported in favor of the establishment of a State Agricultural School. The report was accompanied by a bill, the material provisions of which are as follows:

1. The comptroller to issue certificates of stock to the amount of \$100,000, bearing an interest of 5 per cent, and redeemable in 20 years, to be sold at public auction in the city of New York, to the highest bidder, the proceeds to be applied to the establishment of the school.

2. Three commissioners to be appointed by the governor, to purchase a farm and contract for the erection of suitable buildings for a school, sufficient for the accommodation of 200 pupils, the officers of the institution, and the servants for the farm.

3. The governor and senate to appoint seven trustees, to manage the concerns of the institution, who shall appoint a principal, teachers and overseers, and employ the necessary laborers and assistants, and to prescribe, with the advice of the principal, the police and regulations of the school.

4. The trustees to be a body corporate and politic, and required to report annually to the legislature, or regents of the university, a full statement of the condition of the institution in all its branches. No pupil to be admitted into the school under the age of 14 years.

AGRICULTURE.

(From Proceedings of the N. Y. State Agricul. Society.)

ON MANURES.

COMMUNICATION FROM JESSE BUEL, Esq.

The provident farmer, who knows the value of food to his stock, should equally appreciate the importance of food to his crops: for manure, that is, animal and vegetable matter, is as essential to the growth and perfection of the vegetable, as forage is to the growth and development of the animal. Mere earths, as clay, sand and lime, in whatever proportions they be blended, constitute no part of the true food of plants, although they may be incidentally found in them, and be essential to their structure, as lime is in the bones of animals. It is the mixture of vegetable and animal matters with earths that constitute what we denominate soils; and the quality of soils, in reference to fertility, is in a great measure determined by the quantity of vegetable soluble matter which they contain. Hence fields, long subjected to tillage, without occasional supplies of manure, become exhausted of vegetable food, and refuse a return to the labors of the husbandman. In some districts of our country, particularly in Maryland and Virginia, vast bodies of land, once fertile, have been thus injudiciously worn out, and thrown into commons as useless. Had the owners of such lands obeyed the golden rule, to till no more than they could manure well, their husbandry would have been more profitable, and their fields now fertile and enclosed. In truth, most of us act unwisely in these matters. We cultivate more land than we cultivate well. We are careless in saving manures, and wasteful in applying them. We should readily condemn the husbandman, as a bad manager, who should attempt to *fatten* upon his

farm, twice the number of cattle which it could *feed*. And yet this is precisely the policy which many pursue in regard to their crops. A starved crop is as discreditable to the owner as a starved animal.

In some of the Asiatic countries, where the population is dense, the preservation from starvation of even human beings, sometimes depends upon the fidelity with which every refuse vegetable and animal substance is applied to the soil, as food for plants, destined to subsist the human species.

In Europe, wherever agriculture is prosperous, we see the most scrupulous care used in husbanding and applying this pabulum of vegetation.

Flanders, which has been denominated the garden of Europe, owes much of her prosperity and wealth to her superior management of this source of fertility. Not a particle of fertilizing matter is wasted. The farm stock is fed, summer and winter, in paved stables or sheds, and the urine collected in tanks, and from thence distributed upon the crops. This, with the rape cake which is dissolved in it, constitutes the better half of a Fleming's manure. If applied fresh, it is diluted. It is carried to the fields, and distributed with facility, and forms the best application for clovers and other growing crops, and particularly for flax.

In America, we have been drawing, with reckless waste, upon the supplies of vegetable food which nature has been accumulating for centuries, without husbanding the resources which lie within our reach, and without reflecting on the sterility which we are likely to bequeath to posterity. The old settled districts of our country have already experienced the loss of natural fertility in the soil, and are endeavoring to restore it by a better system of husbandry. The new counties are destined to deteriorate, like the old ones, unless the evil is averted by a timely prudence in economizing manures, and in alternating with grain, more frequently, ameliorating and fertilizing crops, as roots, grasses, &c. Constant dropping will wear upon the hardest rock; and even the ocean would in time become dry, if the fountains which supply it were dried up. Providence endued the earth with fertility, and it is the indiscretion and violence of man which have rendered portions of it sterile and unproductive.

In the few remarks which I have to offer, I propose to consider:—

1. The means of increasing, and preserving from waste, those manures which fall within the reach of farmers generally.

2. The methods of applying them with economy. And,

3. To make some suggestions upon what I term specific manures.

First. Whatever has belonged to a vegetable or an animal, is susceptible of becoming food for plants, and should be converted to this use. And the quantity of such, which is wasted upon a farm, is very great. But the dead matter, in the course of its transmutation into the living plant, undergoes a decomposition, or separation of its parts, the volatile properties are disengaged in the form of gas, those less volatile commingle with the liquids which come in contact with the mass, while the portion that remains, after the fermentation which causes the decomposition of a dung heap has subsided, constitutes but about one-half of the original fertilizing matter; and even this must undergo a further and complete decomposition, in the soil, before it can be taken up by plants, and assimilated with their substance. To save the volatile and liquid portions, for the benefit of his crops, must therefore be an object of great interest to the farmer. If his manure ferments in his yards, and is leached by the rains which fall, the best half of it is irrevocably lost. And if the fermenting process is carried on upon the surface of his fields, the loss is nearly the same—the gases escape, and the liquids benefit but a comparatively small portion of the grounds. To prevent this great loss, till the ma-

nure can be properly applied to the soil, two courses may be adopted, one by retarding fermentation, the other by mixing with the manure earthy matters sufficient to absorb and retain the gases and liquids.

To effect the first object, the barnyard, the site of which should be upon a level surface, may be hollowed in the centre, so as to prevent the escape of the liquids, and to concentrate them from the borders, which may be left broad enough to feed the stock upon, and to afford a dry passage to and from the barn. To prevent the evaporation of these liquids, every species of vegetable litter from the farm and buildings, and the earth from the ditches, swamps and head lands, should be thrown into to absorb them; and as during winter the mass will be frozen, the stalks, straw, &c. may be fed upon this part of the yard. I am satisfied from personal experience, that no artificial puddling is necessary, even upon porous soils, to render such yards capable of retaining water. If greater perfection is desirable, the urine from the stables may be conducted in paved gutters to this reservoir, and a drain may be made to conduct any excess of liquids from it to a tank, from which they may be raised with a pump, and conveyed to the fields when wanted. The liquid manure may be transported in casks, placed upon tumbrils or carts, or conveyed by men, as in Flanders, two parallel poles being fastened to a barrel, below the bilge, and carried by two men. The manure from the horse stables may be spread over the yard, and thus kept from fermenting. Let it be borne in mind, that the best means of retarding fermentation in dung, is to have it constantly trod, in the yard, by the cattle, sheep and hogs; and, in the field, to have it compressed by the teams, which take it from the yard, driving over the pile, and by affording it an abundance of moisture. A loose mass is pervious to heat and air, which soon cause fermentation; but a compact mass, spread over the yard rendered hard by the hoofs of animals, and thoroughly saturated with moisture, will not ferment before the ordinary season of removal; and it often becomes necessary, and is in fact an excellent practice, to cut it with a broad axe or hay knife, to facilitate its removal. If the contents of the yard are applied, as they ought to be, to the spring crops, but an incipient fermentation, at most, will take place before they are removed to the field. To preserve dung in the fields from waste, it may be alternated, in piles, and covered, with earth, particularly with peat earth, or muck, from the swamps, which may be found on most farms. This swamp earth is principally, in its place, inert vegetable matter, a good material for feeding plants, when rendered soluble. But to render it so, it is necessary to combine it with earths, quick lime or barnyard manure, which, by generating heat, and probably inducing new chemical combinations, brings on a fermentation. If mixed with hot stable dung, in the proportion of three of earth to one of dung, in alternate layers, and in a pile four to six feet high, the mass will in a short time begin to ferment, when the whole will be found nearly as serviceable as yard dung. The mixture of earth with manure retards the fermentation of the latter, while the earths receive and retain the fertilizing matters which the manure parts with.

Second. It will be seen from what has already been said, that dung loses one-half of its value by being permitted to exhaust the powers of fermentation in the yard, and very nearly that portion when suffered to rot in piles upon the field, without covering or admixture. The deduction from these premises is, that as far as practicable the fermentation and decomposition should take place in the soil, or in other words, that dung should be ploughed in before the volatile parts have escaped. And the view I have taken of the matter would seem further to imply, what most farmers already know, that the more simultaneous the operations of hauling, spreading and ploughing in are performed, the more are the fertilizing properties of manure preserved. Dung loses much by drying,

after it is carried into the field, or spread upon the ground. The heat of our summers, and the rains which fall (and heat and moisture are the essential agents of putrefaction,) will ordinarily bring on a decomposition in the soil, to meet the wants of the growing crop. Nor are the mechanical effects of long manure upon the soil unworthy of consideration. The heat generated, and the gases evolved, by the fermentation of dung thus buried, render the soil light and porous, more permeable to the young roots, and more pervious to air, heat and moisture, the prime agents of vegetable nutrition. When dung ferments in large masses, the violence of the fermentation is great, and the loss of volatile matter in proportion to this violence. But when the process goes on in the soil, it is comparatively moderate, and the earth and growing plants absorb the volatile and liquid portions which it parts with.

Unfermented yard manures should be applied exclusively to hoed crops, as corn, potatoes, turnips, beans, &c. for two substantial reasons; first, because the culture of these crops tends to destroy weeds. &c. the seeds of which may be brought in with the dung; and secondly, because those portions of the manure which are first separated in the process of fermentation, are better suited to these than to crops which do not require after culture. Unfermented dung, applied in any considerable quantity to wheat or barley, for instance, is apt to cause too rank a growth of straw, which is liable to become rusty and to lodge, and to produce light and imperfect grain. Manures, on the contrary, on which fermentation has exhausted its powers, and such there always will be upon a farm, may be applied to these latter crops, in moderate quantities, with manifest advantage. My practice induces me to believe, however, that the entire benefit of the manure to the hoed crops is saved by applying it to them in its unfermented state; and that it is as beneficial to the wheat when thus rotted in the soil, as it would be if rotted in the ordinary way, in the cattle yard, with the advantage, in the former mode, of the dung being far better incorporated with the soil.

There are three methods in ordinary use, of applying manure. 1. to bury it in hills or ridges; 2. to spread and leave it on the surface, particularly of meadows; and 3. to spread it broadcast and plough it in. The last, I think, is the best mode, not only in reference to the permanent improvement of the soil, but for the advantage of the coming crop. It will be generally found, at least in loose and permeable soils, that the roots of plants equal in length their culm or stalk and sometimes exceed it. At an agricultural exhibition in the capital, a few years since, spears of corn were taken from a box in which they had been grown in a loose soil, the stocks and leaves of which measured but twelve, while the roots measured seven inches. The food of plants is taken up by the spongioles, on the fibres, communicating with the larger roots; and the conclusion seems to be a fair one, that roots, in a common field crop, penetrate every part of the soil, in pursuit of food, ere the crop attains maturity. Hence, if the manure is deposited in hills or ridges, the mouths of the plants are soon found to extend beyond the sphere of its influence, and are at least partially deprived of its benefit; whereas, if it is spread upon the whole surface, these roots are constantly reaching, as they elongate, fresh supplies of food. And I think I may add, as a third reason, that long manure is intrinsically better for these crops, than that which has undergone fermentation. Besides, where long dung is applied in hills and ridges, and a dry season ensues, there is not moisture enough to induce fermentation, and the manure proves injurious, rather than beneficial, to the crop. This will not happen where the manure is applied broadcast.

There is another species of manure available by every farmer, and of no trifling value, and which I am afraid does not receive the consideration it merits: I mean green sward. It has been ascertained that the vegetable matter contained in an ordinary grass lay,

exceeds twelve tons on an acre. This is all convertible into food for vegetables, and is, of itself, if not wasted by bad management, a good dressing for a crop. The same rules apply to this as to other vegetable manures: they are wasted by exposure upon the surface, after having been ploughed under. It is this consideration that has led to the substitution, by many of our best farmers, of fallow crops for summer fallows,—by which they contend, they not only save the fertilizing properties of the soil, but actually gain a crop from the soil. The ploughing for a fallow crop may be performed, upon stiff soils, in the autumn, and upon those that are light in the spring, and the ground may be rolled and harrowed, previous to receiving the crop, which may consist of corn, potatoes, peas, beans or oats. Upon light clover lays, wheat may be sown upon the first fallow, immediately after ploughing, and harrowed in. In this way the food for the crop is placed where the roots naturally search for it, secure from the wasting influence of the sun and winds. Lorain, who I consider the best American writer upon husbandry, and the best writer upon American husbandry, advises, and I am satisfied he does it upon sound principles, that the ploughing which is to follow the fallow crop be superficial, or shallow, so as to leave the unexhausted store of vegetable food below, where it will best subserve the wants of the second crop. Where repeated ploughings and harrowings are given, as is ordinarily the case in summer fallows, the vegetable matter is necessarily thrown to the surface, and much of its fertilizing properties borne off by the winds.

The principal arguments which are urged in favor of summer fallows, are, 1. That they are necessary to clear foul lands of grass and weeds; and, 2. That upon stiff grounds, in particular, they ameliorate, by pulverizing the soil, and rendering it more light and porous. In Great Britain the first consideration may have weight; but with us Indian corn, which is a cleansing crop, and which is planted upon almost every farm, renders a resort to naked fallows unnecessary upon light soils; and upon stiff lays, the cultivated crop gets so much the start, as to be very little affected by the weeds which subsequently spring up. In reply to the second argument, it may be remarked, that stiff grounds are generally retentive of moisture, and that after repeated ploughings and harrowings they are liable to be again rendered compact and hard by heavy rains. Whereas, when the furrow slices are lapped, every furrow becomes a sort of under drain, to receive and pass off the surface water, while the decay of the roots of the grasses renders the soil porous and permeable.

Thirdly. In speaking of specific manures, I am sensible I may be charged with venturing beyond the bounds of prudence. Yet the subject is so interwoven with my views of good husbandry, that I will run the hazard, relying upon the indulgence of my hearers for the errors I may betray. I assume as the basis of my remarks, that all plants take something in common from the soil, in the nature of food; and that in addition, different species, and perhaps all species, take something specific, necessary to their development and perfection, which other species do not require, and do not take. It is upon this assumption alone, that we can explain the natural attenuation of forest trees and grasses, or account for the manifest advantages derived from a rotation of crops in husbandry. The old variety has exhausted its specific food, and hence fails, and a new variety, requiring a different specific food, comes in. The soil, or the atmosphere, must contain the elements of the new plant; and as vegetation is said to be incapable of decomposing common atmospheric air, the soil must be mainly relied on for the specific food of the crop. To illustrate my views, we will say that the elements of plants, generally, and of their products, are carbon, oxygen and hydrogen, all of which abound in common dung; but that wheat, besides those, contain nitrogen. Primitive formations contain nothing

that gives nitrogen; and it would consequently follow, that primitive formations are not adapted to the growth of wheat, unless artificial applications that afford nitrogen, are first made to the soil. New England, with partial exceptions, is a primitive formation, and we very well know it is not congenial to the growth of this grain. The new lands, it is true, will often produce a crop or two, while the animal matter, which centuries has accumulated upon their surface, and which abound in nitrogen, remain unexhausted. And this may likewise happen where the manures applied are such as afford the specific food, as animal matters generally, urine, lime, &c. The failure does not arise from sterility. The straw of wheat may be made to grow as large in New England as in New York: yet the kernel will be small and comparatively shrivelled, for want of the nitrogen essential to perfect the gluten,—the substance which gives peculiar value, and which distinguishes this above all other grain. An extensive primitive region stretches through Pennsylvania and Maryland, contiguous to the great limestone valley. In this line is generally and extensively applied, and its efficacy to the wheat crop fully conceded. Clovers, and some of the other broad leaved plants, seem to find a specific food in gypsum, (sulphate of lime,) which, however, so far as my observation goes, is wholly inoperative upon wheat, rye, timothy, and some other farm crops.

The soil is the laboratory for preparing the food of vegetables, and fitting it for the delicate organs which are to absorb and transmit to the roots. Heat, air and moisture are the agents by which the process is carried on, and water the medium of conveyance. It has been demonstrated by vegetable physiologists, that the fluid matters which present themselves to the mouths of plants, are taken up without discrimination, carried through the albumen or sap wood, to the leaves, the organs of respiration, where the process of elaboration is perfected; that the elaborated or proper sap, then descends through another set of vessels, in the inner bark, depositing in its way the materials for a new circle of wood and a new circle of bark, which in the course of the season become indurated; and that the plant having retained all that is adapted to its wants, the residue is thrown off at the roots, like the excrementitious matter of animals. I shall mention one of the experiments of Prof. Lindley, in corroboration of the latter fact. He took a fresh plant with two prominent roots, one of which he plunged into a vessel of pure water, the other into water containing poison. In a short time the pure water became sensibly charged with the poison, which had been taken up by the root in the poisonous liquid, passed through the circulation of the plant, and voided by the other root in the pure water.

(From the Genesee Farmer.)

CHESS, OR CHEAT.

AS IT IS PRODUCED ONLY FROM ITS OWN SEED, IT
MAY BE DESTROYED.

Greatfield, 3 mo. 1, 1833.

We who reject the doctrine of transmutation, have some advantage over our opponents. If our advice be generally followed, all the chess growing from chess will be destroyed; but this will be all the chess there is, if we are in the right; and then the country will be rid of the nuisance. Now suppose for a moment that we are in the error: they cannot do more good when they are right, than we actually do when we are wrong; but if they are wrong, as we insist they are, they do no good at all, but something worse.

Let us look at the matter a little closer. We hold out encouragement to our farmers to persevere in the extirpation of chess, assuring them that like the dock and the mullein, it cannot spring from any thing but its own seed: therefore destroy all the plants before

they go to seed, and if none be, or one has been, brought from other places, there is the end of one weed.

Very different from this however, is the conduct of our opponents, and those farmers who imbibe their notions, may well say, "What is the use of trying? If we destroy all the chess on our farms, we shall soon have enough more. Wheat, as fast as we affront it with bad treatment, will turn into chess. We cannot clear our farms of it, and we may as well quietly submit to what we cannot avoid."

It must therefore appear that our opponents in this controversy, have not in view the advancement of our agriculture; and while we abstain from prying too closely into the cause of so much zeal directed to no useful purpose, let us hope that something may be found more worthy of them than a horror of having old and long cherished opinions disturbed and broken up.

I think some indeed, may be partly actuated by a love for truth; and I like the candid manner in which my neighbor Samuel Griggs has written on this subject. We are aware however, that almost every kind of grain has, at some time or other, been suspected of turning into other kinds and if I had room and my readers patience, I would lay before him a long list of such wonders. But in place of this, it will be better to offer such explanations as occurred to me while I was reading his essay, and before I read the editor's remarks, for there are various ways in which chess may obtain possession of a field.

It may be laid down as a general proposition that all (English) grain is presumed to contain chess, in larger or smaller quantities, unless the contrary be proved; and no experiment in favor of transmutation ought to be reported, unless special search with regard to chess in the seed grain has been made by some competent person. The propriety of this rule, I think must be admitted by every reasonable man. We have a right to "the whole truth." Unless where particular pains have been taken to extirpate this weed, it is highly probable that not one bushel of wheat entirely free from it, could be found in the whole Genesee country. If wheat or rye contains it, there is little chance for oats or barley to escape, when all these kinds of grain are threshed in the same barn. The tailings which abound with chess, are often scattered over the floor; and even if it be swept, a portion will remain in the cracks and crevices, which a subsequent sweeping may brush up among the grain which has been just threshed, and which may have been clean when it was brought to the barn. Chess is easily hid among other grain; and it has been shown that what many farmers would call clean seed wheat contains chess enough for a crop. A friend of mine the other day, saw some wheat at the mill so remarkably fair that his curiosity was excited, doubting if it could contain any other seed. To resolve the doubt however, he carefully spread out a handful on a board, and found amongst it four grains of chess. When farmers therefore in ordinary cases, speak of clean seed, we are to understand that it is only comparatively, and not positively, clean.

I mean to apply the foregoing rule to the three cases reported by my neighbor; and then we shall see that they afford no kind of proof whatever that either oats, wheat, or rye, turns into chess. A plant that can adopt itself to circumstances so far as to produce good seed, whether it has room to grow four feet high, or only four inches, is hard to exterminate; and chess is of this kind. A subordinate crop of this weed, sufficient to seed the ground, may have grown amongst his oats; but in addition to this consideration, that oat field was frequented by hogs, not wild, I presume, but such as had recently gleaned in wheat stubble which is seldom free from chess. Much of these small hard grains would escape their grinders, and be dropped unharmed on the field. The disappearance of the oats may be accounted for, without the aid of transmutation: those which grow among stubble commonly perish in the winter or spring, and very rarely, if ever, come to maturity.

For that part of his wheat-field, which produced half chess and a quarter smut, S. Griggs admits that the seed was sent to him, and the crop of smut showed that it was foul seed. The wheat as it declined, made room for the chess to grow.

Neither can there be any thing drawn in favor of transmutation from the rye patch. Whether the chess seed all sprouted and came up at the same time with the rye, or whether a part of it lay dormant till autumn, may be a question. Some of it may have ripened among the rye, for new land is not mowed very closely; or it may have been kept under by the rye, or by the scythe, without seeding till the next season. It is well known that many annuals may be converted into biennials, by preventing them from going to seed.

I would not name my friend Dr. D. A. Robinson without some expression of my regard for him, whose testimony would weigh as much with me as that of any other believer in transmutation; but it is not reasonable to expect us to admit parole evidence to prove what we consider impossible, and contrary to the laws of Nature. I would as soon admit parole evidence to prove the actual existence of the Centaur.

It is no new thing to hear of wheat and chess growing together on the same stalk; but such cases have always been reported by those who believed them no deviation from the established laws of Nature, and who may have hoped, or expected, to find such phenomena. Of course their scrutinizing powers would not be put so closely in requisition as his powers would be, who rejected such notions. Had our editor believed with them, he might have been imposed on by Wadsworth's wheat and chess head, and that fallacy have passed undetected. A case in some respects similar also occurred to my friend William Carman. He found in the harvest field, a head of wheat with a spikelet of chess projecting from it which made a very imposing appearance; but he soon unraveled the mystery by discovering that the spikelet had caught in the chaff of the wheat-ear, and had broken off. Had this fallen into the hands of one more credulous than persevering, it might also have been exhibited in proof of the doctrine of transmutation.

Oats and spring wheat not being winter killed, often stand more evenly and regularly over the field than other wheat; of course the chess has less room to grow; and commonly less of its seed is scattered on lands of this description.

Wheat that is eaten off when the stalks are eight or ten inches high, would consequently allow the chess which it had overshadowed and kept under, to spring up; but the mind that can infer from these appearances that the chess grew from the wheat roots and not from its own roots, must make but little use of proof in forming its opinions, and be easily satisfied with strange things.

The case of A. Burr's new wheat-field is prematurely reported. It would be some satisfaction to know wherein wheat-chess resembles wheat more than rye; wherein rye-chess resembles rye more than wheat; wherein flax-chess resembles flax; and why the offspring of that flax seed which was cleaned twenty years ago in Palmyra, has produced no flax chess in that long course of time? But I hope not for such concealment while all our arguments remain unrelated, and while facts of the most stubborn kind to our opponents, are left entirely unnoticed.

W. H. has given a circumstantial account of two wheat crops raised in succession, among which not one kernel of chess was found; and if we knew of no other experiment of the kind, this alone ought to shake the belief in transmutation. But when to this, are added the numerous instances already cited, of a total exclusion of chess from whole farms for many years together, and given on the most respectable authorities,—the tide ought to set still stronger against that belief. Neither is this all: in one wheat growing district where chess was formerly a trouble-

some weed, but from which the farmers were wise enough to expel it, nearly twenty years have elapsed since its final disappearance.* Evidence of this weight and magnitude, must preponderate in every well balanced mind.

But it is intimated that the experience of others in the present age or in the past, is to be outweighed and nullified by new experiments about to be made in these days: Grains of wheat, by some alchymic process, partly killed and partly kept alive, are to produce chess-bearing plants of the most prolific kind! For the reputation of our farmers I am glad that so few are implicated in this *manufacture*; and I hope not to be accused of wishing to depress *American talent*, when I apprise them that their day of triumph is more remote than they imagine. They will find, like the Baron Palissy, who wrought sixteen years to perfect his enamel, that "the road to Arts is long."

Suppose, having sown this *prepared wheat*, that they find chess growing in the place, will it prove that the wheat turned into chess? No more than it would prove that the wheat had turned into red-top, or spear grass, should such happen to spring up from a few seeds dropped from their sleeves. There is much uncertainty in conducting such experiments in a neighborhood where chess is abundant. We may have clean seed and clean ground, but who can say that no chess will be dropped there by accident? Selah Chapin raised seven heads of wheat from chess, as he avers. Many of our opponents however, no more believe that chess can turn into wheat than we do; but here a difficulty stands before them: they must either admit that statement to be correct, or admit that people (including themselves) may be easily deceived in making such experiments.

Suppose then that a result, in conformity to such overweening confidence, should be reported in the same unqualified manner as that in which the progress of the experiments has been announced, ought we to accept such report? No honest inquirer after truth would put such petty experiments,—liable to be interfered with, changed, and reversed by any animal that can carry and drop a few seeds,—in competition with facts, more numerous, quite as well attested, and which could not possibly have been deranged or perverted by accident or evil intentions. I have already noticed some farms on which no chess had been found among the wheat crops in thirty years. These periods included favorable and unfavorable seasons; much wheat must have been dropped in stubbles, and more or less of it left uncovered in every field that was sown; yet none of it turned into chess. Experiments so extended can admit of no mistake. No countervailing reports can be conclusive, and none ought to be accepted †

Some doubt whether pigeons disgorge chess. Incredible sometimes arises from knowing too much to be imposed on, and sometimes from knowing too little to understand the subject. The *crop* of the pigeon is the *basket* in which it carries food, often to the distance of 60 or 80 miles, every day for its young; and by means of a muscle which acts at will, it can empty that *basket* as readily as we can empty our baskets which we carry in our hands. In Winterbottom's History of America, this faculty of the pigeon, is given as a part of its *generic character*. Near Philadelphia, the opinion has been prevalent among farmers, that these birds feed on garlic (*Allium vineale*) which has much infested the fields, but that they eject it whenever they find better food; and one of my neighbors complains that a bad weed has been introduced on his farm by the pigeons, and he no longer permits baiting places to be made for them. The inquiry now arises, would a pigeon, whose *crop* was

filled with husky chess, prefer retaining it to eating good wheat? Its power to make the exchange is certain, and I have no doubt of the correctness of its taste. D. T.

HORTICULTURE.

(For the American Farmer.)

THE LILY OF THE HOLY SCRIPTURES.

I have lately noticed an attempt to impress the belief that the lily of the Old and New Testaments is not (as has been supposed) the common white lily, (*Lilium candidum*) which is a native of Palestine, but the *Amaryllis lutea*. I should have been better satisfied if the writer of that paragraph, had taken the trouble to show that his opinion was more conformable to the texts which relate to that plant; but as this has not been done, I must take the liberty to dissent, and I am willing to give my reasons for so doing.

The *Amaryllis lutea* is a little plant with one yellow flower on a scape about six inches high, and inferior in brilliancy and beauty to the majority of bulbous plants cultivated in gardens. But the lily of the scriptures is referred to, as one of the finest flowers of that country: "Solomon in all his glory was not arrayed like one of these." Mat. 6. 29. In the Song of Solomon, it is placed on an equality with the rose: "I am the rose of Sharon, the lily of the valleys." 2. 1. I find no reference to its *color*, but it was very fragrant: "His lips, lilies, dropping sweet smelling myrrh." Song 5. 13.

All these particulars agree well with the white lily, but not with *Amaryllis lutea*; and how this little flower could be the subject of the following references, it would require some ingenuity to discover: "As the lily among thorns, so is my love among the daughters." Song 2. 2. "He shall grow as the lily, and cast forth his roots as Lebanon." Hosea 14. 5. The former text shows it not too diminutive to compare with the thorn; and the latter text, evidently refers to a plant of vigorous growth. A FLORIST.

(For the American Farmer.)

GRAFT AND STOCK.

I could be well content to believe, if I could find reasonable proof, that *trees have a determinate period of existence*; and that a graft taken from an old one must die in the same age as the parent stock. I have not yet made the discovery however; and the argument for this opinion, copied into your valuable paper at page 397 of volume 14, is what logicians call a *non sequiter*, or an inference not warranted by the premises, if "all the new kinds so remarkably clean and healthy" are the offspring of the common apple and Siberian crab, as I understand them to be; for then they are *hybrids*, not belonging to the same species as the old varieties, but differing in their natures; and having never been like them, it necessarily follows that these *mules* furnish no proof that the others have ever changed, or deteriorated.

There are two other opinions in that essay on the varieties of "FRUIT," in which I can scarcely join with the intelligent author. He says, "the animal can have but one father—the vegetable may have a plurality of fathers." I suspect it would be hard to show such a difference. It is a belief among some breeders, that pups or pigs of the same litter may have different "fathers," but I never heard of a pup or pig supposed to be the offspring of two "fathers." Why then should we believe that one seed of an apple should be fecundated with the pollen from two other trees? I incline to think that the seed is fecundated at once; and by a particle of pollen so small as not to require the assistance of any other particle. If there is any just analogy between the seeds of plants and the eggs of insects or of fishes, some light may be thrown on this subject from that quarter. The

queen bee from once pairing, lays from 70,000 to 100,000 fertile eggs; and a single female of several kinds of fishes, produces at one time more than one million of eggs. The quantity of *semen* to impregnate one egg must therefore be almost infinitely small; and we can scarcely imagine that any definite or assignable quantity, is too small for the purpose.

The other opinion with which I am not entirely satisfied, is, that "the roots of a grafted or budded tree take the habits of the scion." The circumstance so frankly expressed that the quince and the paradise apple are exceptions to this rule, shows that the subject deserves to be more closely examined. The known effects of the grafted branches on the stock is not very great; and where the graft has been set a few feet from the ground, nothing is more common than a visible, and often a remarkable, difference in the size of the trunk, commencing exactly at that point. If then the branches have so little control over the size of the stock, we ought least of all to expect that they would give *shape* and *direction* to the roots. Some years ago, I had a variety of the domestic plum, remarkable for sending up sockers from its roots, far and wide; and for want of better stocks, I grafted into them many varieties of the plum, and about half a dozen kinds of apricots. On examining these however, I cannot discover that the branches have restrained the roots in any manner whatever; and it would be strange if they should, for this supposed control would be withstood and resisted by the first sprout that appears. Z.

(For the American Farmer.)

ANEMONE PAVONIA.

Greatfield, Cayuga Co. N. Y. 3 mo. 22, 1833.

In the 14th volume, page 277, of the American Farmer, I gave some account of the *Anemone pavonia*. It continued in flower till the severe frosts marred its beauty; and then, fearing that the root might become frozen and perish, I placed thin inverted suds on each side of it, and brought their edges close together, so that the upper parts of the scapes and the longest leaves only, were uncovered. Over these I threw a light covering of evergreens, and left it to its fate. Since the middle of winter it has been well protected by the snow; but a general thaw having occurred within the last week, yesterday on lifting the evergreens, I found the anemone had been vegetating during its seclusion; and several new scapes had grown five or six inches long, though bent and crooked in consequence of their confinement. Should the weather continue mild a few days longer, it will be in full bloom.

I should have been afraid to trust this fine plant in the open ground during the winter, if I had not had two others in the house for safe keeping. On the approach of severe weather, these were *potted*, and taken into a common sitting room. Every necessary attention was paid to them in watering, &c. but the air proved to be too dry, and the flowers as well as the foliage began almost immediately to decline. D. T.

(From McIntosh's (British) Flora and Pomona.)

A NEW FRUIT.

"*Berberis Parviflora* deserves to be particularly noticed, as it is likely to become an addition of no ordinary description to the exotic fruits already in this country, the fruit being very fine, and used in its native country, (the Straits of Magellan) for making tarts and puddings.

"It is described as growing from seven to eight feet high, producing fruit abundantly; the berries being nearly as large as those of the black cluster grape, produced singly on short footstalks. This desirable plant was sent home by Mr. James Anderson, the intelligent and enterprising botanical collector."

* American Farmer, vol. xiii. p. 395.

† It has been suggested that they may cut the stalks on one side of a wheat plant to make it sprout up and yield chess while the other side yields wheat. Let them produce the plant!

TRANSPLANTING FROM HOT BEDS.—After raising plants in the hot-bed some little experience is necessary to insure success in removing them to open ground. The common error which is committed in this business is, planting them out before the weather becomes warm enough to keep up the vegetable circulation; and the consequence is, that during the rainy weather the plants look water soaked and perish; but if the weather continues dry and cold, tender plants will wilt and die. Each plant requires a certain degree of heat to cause it to flourish—some more and some less, and due reference should be had to this in removing them. Cabbages thrive best in cool, moist weather; but melons and cucumbers require a greater degree of heat, and of course should not be transplanted until the weather becomes warm enough to cause the yellow locust to be in full leaf.—*Genesee Farmer.*

RURAL ECONOMY.

(From the Genesee Farmer.)

A BEE STORY.

A friend told me the other day a bee story, and were he not a man on whose word I can strictly rely, I should set it down as a real Munchausen. Such as it is you shall have it.

In Wythe county, in Virginia, in a spur of the Alleghany mountains, called the "Tobacco Row," is a perpendicular ledge of rock fronting the southeast, about fifty feet high—an open sunny situation. About thirty feet from the base, a horizontal crack or fissure opens in the rock, from half an inch to six inches in width, and extending near eighty feet in length. How deep this fissure extends into the mountain is not known, as no one has ever examined it. *This fissure is full of bees!* Their numbers are so great, that in the summer time they hang out in huge clusters for several feet, above and below the fissure, in its whole length. A short distance above are two other cracks, containing earth, in which grow some little chinquapin bushes, and these are covered with bees. They frequently go off in huge swarms, like a barrel or hog-head in bulk, and are often compelled to return, finding no place large enough to contain them. In the spring previous to commencing their labors, the dead bees, remnant of comb, and cleanings of the habitation which are brought out and dropped by them, make a *winnow* of a foot in height the whole length of the opening.

My informant saw it in the month of June, when immense numbers of bees were out on the surface, making great patches of rock black with their swarming masses. The oldest inhabitants say that the first settlers found the bees there, and the Indians told them that their oldest traditions knew nothing of its origin. *"It was always there."*

No one has ever been found bold enough to attempt its plunder, or to examine the place where they are. It is, in fact, too dangerous an enterprise to meddle with.

If these facts be so, and I cannot doubt it, does it not form rather a new feature from that generally received in the history of the bee? *I rather give there is more than one queen in that hive!* By the way, I fear that I am going to have all this bee discussion to myself. But we'll see.

Do none of the correspondents of the American Farmer live near this great bee-hive? If so, I should be much gratified to hear further about it.

CLUES.

SCALDING HOG.—A gentleman of experience and observation desires us to make known, for the benefit of farmers, a mode practised by him of scalding hogs. Instead of putting cold water or a *hes* into the hot water, as is the general practice, he washes the hog in cold water previous to scalding it. It matters not

how hot the water may be with which the hog is scalded, if cold water is first used in the way prescribed, the hair can be taken off with ease and neatness. No danger need be apprehended of the hair becoming set, as is often the case when this mode is not resorted to, owing to a particular temperature of the water.

The gentleman who communicated to us this mode, says he has practised it for more than twenty years, and has not during that time, experienced any difficulty in scalding hogs.

In dressing a young pig for roasting, he first dips it in cold water, and then in hot, by which process he is enabled to remove the hair with the least possible trouble.—*Wyoming Herald.*

FEATHERS.—Feathers or down intended for use, should be plucked as soon as possible after the bird is dead, and before it is cold, otherwise they are defective in that elasticity which is their most valuable property, and are liable to decay. The bird should besides, be in good health and not moulting, for the feathers to be in perfection; and being plucked, and a sufficient number collected, the sooner they are dried in the oven, the better, since they are else apt to heat and stick together.—*Moubray's Treatise on Poultry.*

MISCELLANEOUS.

(For the American Farmer.)

A REMARKABLE SNAKE.

Colonel Hamilton, first British commissioner to Columbia in 1823, on his journey from Bogotá to Popayan, arrived at El Aneon, a gentleman's country house, where he was invited to remain with his suite two or three days to rest themselves before they undertook the passage over the *Judes*. After dinner the colonel and his secretary were invited by Dr. Borrero to go out to shoot, as the woods on the estate were well stocked with wild boars and deer. The following is his account of a remarkable snake.

"On returning home through a large chocolate plantation, the negro pointed out to us a snake coiled up and apparently asleep. I told the doctor I should like to have a shot at him, which I did with my left barrel, in which I had swan shot, and only wounded him in the tail. The moment I fired, he sprang up, looked round, and espied us; on which he came directly toward us, sweeping along, his head erect, and about three feet from the ground. We all now began to be alarmed; and the doctor ordered us to retire a few yards behind a large tree while he advanced to give him the contents of two more barrels, which movement was immediately executed; and when the snake was distant about ten yards, the doctor and myself fired, and cut him nearly in two, each barrel being loaded with seven or eight small slugs. We then shouted victory, and the rest of our party, being unarmed, came up to us. We examined our fallen enemy, and it proved to be a snake called *the aques*, from having a black cross like an X all along its back. This snake is considered by the *Crooles*, one of the boldest and most venomous in South America. He measured about six feet and a half in length, and was as thick as my wrist. Had I been aware that this had been so bold and venomous a snake, I certainly should not have disturbed his *siesta*. The doctor stated that several persons in the province had lost their lives from the bite of *the aques*, and that he had seen them considerably larger."

Colonel Hamilton again met with this kind of snake when he was travelling down the valley of Cauca. "As we were going to cross a stream; we observed a large snake swimming towards us; and when he arrived near the bank he stopped, apparently to watch our motions, with his head and part of his body out of water. I then observed the black cross on his neck,

and knew it was the snake called *the aques*. A negro who was passing on foot at this time, agreed for a dollar to endeavor to kill the reptile. For this purpose he went a short distance in the rear, and cut a large long bamboo with his manchette, and advanced to the attack of the snake, who had remained quiet in his position with his eyes fixed on us. As the negro approached the aques, he put out his forked tongue, and raised himself higher in the water, as if preparing to make a dart at his enemy, which the black observing, retired a few paces, and then told me he was afraid to attack it, as it was prepared to spring on him. In this position the negro and the snake remained for two or three minutes, watching each other, when suddenly the aques turned round to swim to the other side of the river. The moment the negro observed its head turned from him, he rushed to the bank, and gave the aques two or three tremendous blows with the bamboo, which made him turn on his back, and the negro followed up his attack and succeeded in killing his enemy. This aques measured six feet in length. The black brought it to me on his bamboo, and appeared much elated at his victory, and not less so when he received his reward."

(From the Boston Daily Advertiser.)

BIRDS AND INSECTS.

We have already intimated our opinion, that the labors of the scientific ornithologist are of far more practical utility, than the casual observer might suppose; and that, even in the business of legislation, a regard to his researches might prevent many errors, which may much affect the public welfare. There is no denying, that there has been no lack of legislation on the subject of irrational living things; fishes have received an undue share of attention in consequence of their negative merit of being good to eat, while the beasts have been made the object of attentions of a different sort; the several towns being duly authorised to raise money to be expended as a bounty for destroying some of the least popular of the race. Without inquiring into the propriety of this policy here, we must affirm that the legislation on the subject of birds has been marked by some essential errors, which have led to real evil. We have already alluded to the law of 1817, by which woodcocks, snipes, larks and robins were protected at certain seasons of the year, while war to the knife was declared against crows, blackbirds, owls, bluejays and hawks: these last were treated as a sort of pirates, subject to suspension at the yard arm with the least possible ceremony. It so happens that the character of these very birds has been singularly mistaken: for while the ordinance of legislation has been thus systematically levelled at them, they, on a principal which man would do extremely well to imitate, have been returning good for evil; they have been diligently engaged in extirpating all sorts of vermin, while never were the veriest vermin half so ill treated by the human race. The crow, for example, who is generally regarded as a most suspicious character, has had great injustice done him; in the spring, when the ground is moist, he lives in a state of the most triumphant luxury on grubs: he eats the young corn, it is true, but it is a necessary of life to which he never resorts, except when his supply of animal food is shortened. After the corn is tolerably grown, he has nothing more to do with it; and in any stage, he destroys at least five hundred pernicious grubs and insects, for every blade of corn which he pillages from man. In the Southern States he is regularly permitted to follow the ploughman, and collect the grubs from the newly opened furrow: his life is thus secured by the safest of all tenures, that of the interest of man in permitting him to live. There is scarcely a farm in England without its rookery; the humid atmosphere multiplies every species of insect, and these birds reward man for his forbearance by ridding him of legions of

his foes. By a policy like that which dictated the revocation of the edict of Nantz, they have occasionally been exposed to the mischievous propensities of raptorial boys, who, as far as utility is concerned, are not to be compared with crows, but the error of this step soon became obvious, and they are now received with a universal welcome. The hawk enjoys a doubtful reputation in the hen roost: he sometimes destroys the chickens, but with the consistency of man does not like to see his infirmities copied by another; and by way of compensation demolishes the fox, which eats twenty chickens where he eats one; so that it is hardly the part of wisdom to set a price upon his head, while the fox, a hardened knave, is not honored with a penal statute. How the owl came to be included in this black list, it is vain to conjecture; he is a grave, reflecting bird, who has nothing to do with man, except to benefit him by eating weasels, foxes, racoons, rats and mice, a sin for which most householders will readily forgive him.

In some parts of Europe, he is kept in families like the cat, whom he equals in patience, and surpasses in alertness; hour after hour he may be seen watching for his prey, with the air all the while of being completely absorbed in some mathematical problem. Another of these birds, the blackbird, is the avowed enemy of grubs, like the crow; in the middle states, the farmer knows the value of his company to pluck them from the furrow; while other less painstaking birds collect the vermin from the surface, his investigations are more profound, and he digs to the depth of several inches in order to discover them. When the insects are no longer found, he eats the corn, as well he may, but even then he asks but a moderate compensation for his former services: five hundred blackbirds do less injury to the corn, than a single squirrel. The last upon the catalogue of persecuted birds is the blue jay: whoever watches him in the garden will see him descend incessantly from the branches, pouncing every time upon the grub, his enemy and ours. These are facts which are derived from the researches of the ornithologists; and they certainly show, that a knowledge of the character and habits of birds may be of consequence in legislation, if it should do no more, than to give protection to the innocent.

We have already seen that the act to which we have referred protects some birds certain seasons of the year; among others the robin who lives on insects and worms, and has no taste for vegetable diet, and the lark, who is extremely useful in his way; the only wonder is, that it should have been thought expedient to allow them to be shot in any season. The quail, another of the privileged class, has no title to be named in company with the others; in the planting time, he makes more havoc than a regiment of crows, without atoning for his misdeeds, by demolishing a single grub. Nor is the partridge a much more scrupulous respecter of the rights of property; though, as he lives in comparative retirement, he succeeds in preserving a better name for honesty.

There are some other of our most familiar birds; of which a word may here be said. Every body has observed the little goldfinch on the thistle by the wayside, and wondered perhaps, that his taste should lead him to so thorny a luxury; but he is all the while engaged in devouring the seed, which but for him, would overrun the grounds of every farmer. Even the bobolink, a most conceited cockeomb, who steals with all imaginable grace, though we are bound to say that he is much more attentive to our southern neighbors in this particular, than to us, destroys millions of the insects which annoy the farmer most. All the little birds, in fact, which are to be seen about the blossoms of the trees, are doing us the same service, in their own way. Perhaps there is no bird which is considered more decidedly wanting in principle, than the woodpecker; and certainly, so far as man is concerned, there is none more conscientious. So long as a dead tree can be found for his nest, he

will not trouble himself to bore into a living one; whatever wounds he makes upon the living, are considered by foreign gardeners as an advantage to the tree. The sound tree is not his object: he is in pursuit of insects and their larvæ. In South Carolina and Georgia, forests to a vast extent have been destroyed by an insect, which would seem as capable of lifting a tree as of destroying it; the people were alarmed by the visitation, and sagaciously laid the mischief to the door of the woodpecker, until they found that they had confounded the bailiff with the thief; since they ascertained this, the people of Georgia have adopted towards this bird a line of policy very different from that which they pursue towards the Cherokees.

The injury arising from the loss of a single crop is hardly to be estimated. The experience which is taught us by our own misfortune is very dearly bought; and we think that if we can derive it from others—if, for example, we can learn from the ornithologist, the means of preventing such injury, as in many instances we may, the dictates of economy combine with those of taste, and warn us not to neglect the result of his researches.

(From the Genesee Farmer.)

MOUNTAIN RICE.

In the Library of Entertaining Knowledge, the following account is given of the *Mountain rice*, and of an unsuccessful attempt to introduce its culture in England.

"*Mountain rice* thrives on the slopes of hills and in other situations where it can receive humidity only occasionally. Dr. Wallich, the able successor of Dr. Roxburgh as superintendent of the botanical garden at Calcutta, sent to London a few years ago some specimens of *rice* grown on the cold mountains of Nepal. These seeds were furnished to him by the resident of the East India company in that district, and were recognized by the doctor as *mountain rice*. The degree of cold which this plant is qualified to bear is very great. According to the information collected on the subject by Dr. Wallich, the cultivators consider their crop quite safe if the growth of the plants is advanced five or six inches above the surface at the time the winter snows cover the ground. It is probable that the slow melting of the snow is beneficial to the growth of the plant which advances with great vigor on the return of spring.

"A knowledge of these circumstances might have led to the opinion that this variety of *rice* could be naturalized in England, if the attempt had not already been fairly made by one well qualified for conducting the experiment. Samples of six different sorts of the *mountain rice* which had been procured by Sir John Murray, from the neighborhood of Serimagar at the foot of Mount Imaus, were on the occasion alluded to, presented by the board of agriculture to Sir Joseph Banks, who planted each kind in a separate bed, in a sheltered spot with a south aspect in his garden at Spring Grove. The grains which were sown very thin on the 21st of May, speedily sprang up, and the plants tillered so much that the beds put on the appearance of compact, dense masses of vegetation; each plant having from ten to twenty offsets. Although the blades grew vigorously, attaining in a short time to the length of two feet, there was never any symptom of a rising stem; and if the ground was not watered, either by rain or artificially every three or four days, the plants began to assume a sickly hue. In this manner vegetation proceeded, without the smallest symptom of their perfecting themselves by fructification, when the plants were suddenly destroyed by an early night frost in September. Some of the plants which had been transferred to pots and placed in the hot house at an early period of their growth, soon died; while others which were sown originally in a hot house, produced

ears and flowered, but the blossoms dropped without perfecting any seed.

"The conclusion to which Sir Joseph Banks arrived from these experiments was unfavorable to the cultivation of *rice* in this country as a grain bearing plant." Part 29, p. 87.

With all due deference to so eminent a name, I must think this conclusion unwarranted. It appears from the information collected by Dr. Wallich that the *mountain rice* is a *biennial* plant; and that to have it well rooted in autumn is necessary to insure a good crop. In the experiment however, the *rice* was not planted till near the close of spring. If common winter wheat had been treated in the same manner, a conclusion might have been drawn with equal propriety, that the climate of England was unfavorable to the growth of wheat.

I think also that our author has been too easily satisfied on this point: and though writing so lately as the early part of the year 1832, he appears not to have known that any thing further had been done in England; or that this variety had been successfully introduced on the continent of Europe. The annexed account is from London's Encyclopædia of Plants, published in 1829.

"The dry or *mountain rice*, cultivated in Ceylon, Java, and of late in Hungary, has the culm three feet high. It is sown on mountains and in dry soils. In the hilly parts of Java, and in many of the Eastern Islands, the *mountain rice* is planted upon the sides of hills, where no water but rain can come; it is however planted in the beginning of the rainy season, and reaped in the beginning of the dry season. It is entirely unknown in the western parts of India, but is well known in Cochin-China where it thrives in dry light soils, mostly on the sides of hills, not requiring more moisture than the usual rains and dews supply, neither of which are frequent at the season of its vegetation. In Hungary *rice* has not been long cultivated: the *mountain* sort has been chiefly tried, and that in the manner of our barley or summer wheat. In England a crop of *rice* has been obtained near Windsor on the banks of the Thames. In Westphalia and some other parts of the south of Germany [the common?] *rice* has been long cultivated; there it is sown on lands that admit of irrigation. From long culture in a comparatively cold country, the German *rice* has acquired a remarkable degree of hardiness and adaptation to the climate; a circumstance which has been frequently alluded to, as an encouragement to the acclimating of exotics. It is found, Dr. Walker remarks (*Essays on Nat. Hist*) that *rice* seeds direct from India will not ripen in Germany at all, and that even Italian or Spanish seeds are much less early and hardy than those ripened on the spot."

Some years ago when I have been in the western parts of Indiana I was told by a very respectable and intelligent man that the *mountain rice* had been cultivated by one of his distant neighbors with success. The product was said to vary from thirty to sixty bushels to the acre in the rough, which might diminish to one third of these quantities by hulling. I have learned nothing in regard to its culture since that time.

There can scarcely be a doubt that the *mountain rice* would succeed in the neighborhood of our lakes; and though it would not probably supersede any of our other crops, we might be able to raise enough for home consumption. I have wished to try the experiment; and a notice that a few seeds of this variety were wanted, was given in *The American Farmer* last year, but no answer has been returned from any part of the United States. D. T.

MANURE FOR WHEAT.—Dr. Joseph E. Mose, states the opinion, that animal manures are particularly necessary for wheat crops, because gluten, the elastic proximate principle of wheat, contains nitrogen, which assimilates to its animal bodies.—*Silliman's Journal*.

Prices Current in New York, March 30.

Beeswax, yellow, 18 a 20. *Cotton*, New Orleans, 11 a 13½; Upland, 10 a 12; Alabama, 10 a 12½. *Cotton Baggins*, Hemp, yd. 13 a 24½; Flax, 13 a 14½. *Flax*, American, 7 a 8. *Flax seed*, 7 bush. clean, 15.00 a 15.25; rough, 13.00 a —. *Flour*, N. York, bbl. 5.62 a 5.75; Canal, 6.12 a 6.37; Balt. FINE MALTESE JACK FOR SALE.

The Subscriber has for sale (on commission) a fine Jack of the breed of the Knight of Malta and Royal Gift. He is six years old, a very powerful animal, a sure foal getter, very gentle and easily managed. Price \$200, delivered in Baltimore. The following are the dimensions of the animal furnished by the owner:

- 4 feet 2 inches in height, (12½ hands)
- 5 " 10 " round the body
- 3 " 6 " round the neck
- 1 " 4 " round above the knee
- 1 " 0 " round the knee

Apply to **I. L. HITCHCOCK,**
American Farmer Office and Seed Store.

ORCHARD AND HERDS GRASS SEED

For sale at the American Farmer Office and Seed Store, by **I. L. HITCHCOCK.**

Clean Orchard Grass Seed \$3 per bushel. A lot of this seed imperfectly cleaned will be sold at \$2.50 per bushel. Herds, \$1 per bushel.

SILKWORM EGGS

For sale at the American Farmer Office and Seed Store, at \$1 per thousand. They can be sent safely by mail if ordered immediately, before the weather becomes warm. **I. L. HITCHCOCK.**

BUFFALO BERRY TREE OR SHEPHERDIA OF THE ROCKY MOUNTAINS.

When our friends send to us for Gooseberry Plants we can very conveniently pack with them one or more of these truly splendid trees, which, when in bearing, are literally loaded with delicious red berries, resembling the Antwerp Currant, and set as thickly on every twig as kernels of corn on the ear. Price \$1 each.

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at \$1 per bushel.

I. L. HITCHCOCK,
American Farmer Office and Seed Store.

ANTWERP RASPBERRY AND CURRANT BUSHES—GENUINE.

Just received a few plants of the Red Antwerp Raspberry, best kind, at 25 cents each, or \$2.50 per dozen. Common kind usually known by this name, and bearing fine fruit, 12½ cents each, \$1.25 per dozen, or 95¢ per hundred.

Genuine Antwerp or Large Dutch Currants, 25 cents each, or \$2.50 per dozen.

Address **I. L. HITCHCOCK,**
American Farmer Office and Seed Store.

BENE SEED.

Just received at the American Farmer Office and Seed Store, a supply of fresh seed of the Bene Plant, so celebrated for its medicinal virtues in the cure of the summer or bowel complaint of children.

HERBEMONT ON THE VINE AND WINE MAKING

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States. By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents

PUBLIC SALE OF DURHAM SHORTHORN-ED CATTLE AND HIGHLY IMPROVED SHEEP

Will be sold on Wednesday the 2d day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd. The highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEWERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young Lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand. **DAVID MEADE, Administrator.**

April 5,—83

DOUGLAS' WHEAT MACHINE.

Made by Z. Booth, New York.

The Subscriber has the agency for vending this very superior implement, and has also a sample of a two and four horse power machine, which he will exhibit at his warehouse, Camden street, and also testimonials of the highest respectability, who have a practical knowledge of their worth. **HENRY W. GRAY.**

March 29—24

FIELD AND GARDEN SEEDS, &c.

J. S. EASTMAN offers the following Seeds for sale, viz. CLOVER, TIMOTHY, MEADOW OAT GRASS, MILLET, LUCERNE, COW PEAS, LARGE YELLOW PUMPKIN, and EARLY WHITE CORN.

Also a general assortment of GARDEN SEEDS, and WHITE ONION SETS.

Likewise in store, a general assortment of AGRICULTURAL IMPLEMENTS, embracing almost every article in the farming line, which he will sell low for cash or approved city acceptances.

He must decline opening any new accounts, except with those who will be liberal customers, and can give good references; and all such accounts he expects to be promptly settled once a year; and those who have accounts standing on his books over one year, are desired to settle the same. All Grass Seeds must be considered cash. Liberal discounts will be made on all implements purchased by merchants and others to sell again. Feb. 15.

SINCLAIR AND MOORES NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Buses, (among which is the much admired Greville,) double Altheas, Honeysuckles, Corcorus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Alanthus, white flowering Horsechestnut, and silver-leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Buses, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets. Feb. 22.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—An improvement will be noticed in wheat and corn, but millers are unwilling to purchase wheat at present prices. Howard street flour was selling from wagons at \$5.37½ yesterday. In other articles there appears to be no change though there is a steady business doing.

Tenney's.—Seconds, as in quality, 3.00 a 3.00; do. ground leaf, 5.00 a 9.00. Crop, common, 3.00 a 5.00; brown and red 1.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00. Fine yellow, 18.00 a 26.00. Virginia, 4.00 a —. Hapahannock, 3.00 a 4.00. Kentucky, 3.50 a 8.00. The inspections of the week comprise 417 bbls. Md.; and 35 lbs. Ohio—total 452 bbls.

The American Farmer,

Edited by GEORGE B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum: due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect at THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, APRIL 12, 1833.

We select for publication another letter, from among many, on the subject of the patronage of the American Farmer. We know not how it is, but so it is, that the first and greatest subject of human interest receives the least attention. What nation is there on the face of the earth, either great or prosperous, in which agriculture is neglected? And we may reverse the proposition: What nation is there with improved agriculture, that is not prosperous and powerful, and whose people are not happy and comfortable? As it respects the dissemination of knowledge, through the medium of the press or otherwise, it would seem that the subject of most importance to the whole community would naturally be the first to receive attention, and the one that would demand the greatest portion of it too; and therefore, that the present position of politics and agriculture would be reversed in this respect. But so it is. There are some twelve or fifteen hundred political papers in the United States, and only eight or ten devoted to agriculture; and the patronage of all these too, if concentrated upon one would not be greater than many a single political paper receives, and would then be no very great object. We like the spirit of the following letter on this subject.

Eluck Walnut, Va. March 28, 1833.

Dear Sir.—Inclosed you will find ten dollars, my subscription for the American Farmer, for the 14th and 15th vols. By way of atonement for delay in paying for the year just ended, I now pay for that and the one just commencing. I wish you success in the publication of a work which deserves the patronage of the agriculturists of the United States, and to which I would gladly lend any aid in my power. I can but observe, that it is no less a mark of bad taste, than bad economy, to contribute to the circulation of political papers, of all grades, sizes and qualities, which serve but to inflame the passions, delude the understanding, and corrupt the morals of the community. For, as political papers are conducted at present, without regard to principle, or respect for private or public worth, abusing without discrimination, or lauding beyond measure, whoever approves or disapproves, whom they applaud or condemn, contending for consistency and principles, without the possession of either; while a paper admitted by all conversant with its merits, to be really valuable, and eminently so, should decline in patronage, meet with a precarious support from the American people, especially the agricultural part of them. This should not be so; are agriculturists wise enough, are they alive to the true interest and glory of their country? the worn, guiled, and piny barrens of Virginia at least say no. While her politicians boast of her proud and lofty standing, why are her best citizens selling their worn and worthless lands, and flocking to the West and South? Sir, the reason is obvious, the neglect of all inquiry on the subject of vital importance, while they are all distraction and confusion on some eternal political bubble; which, though it last but for a week, will but make room for a successor. Thus in watching the folly of others, we give uncontrovertible evidence of our own. If one-tenth of the time and money that has been expended in Virginia in the discussion of abstract principles, and boasting of Virginia influence, Virginia doctrines, and Virginia patriotism, had been expended for the last twenty years in the pursuit of agricultural and mechanical information and improvements, I think I may venture to say Virginia would not have retrograded in her influence and numerical importance in the union. Please excuse this digression, and accept assurances of my best wishes.

SPECUTIA ISLAND WHEAT—hard to beat.—Some small parcels of wheat, remainder of the crop of S. W. Smith, Esq. were recently sent to the Baltimore market for sale. The four parcels weighed 641, 651, 641 and 65 pounds; were premiums awarded for weight and quality, this would be hard to beat!

STOCK OF THE LATE R. K. MEADE.—An important error occurred in the advertisement of the sale of the cattle, sheep, &c. belonging to the estate of the late Richard K. Meade, Esq. in our last number. The day of sale should have been the *twenty-ninth* of May, instead of the second, as stated in the advertisement.

We take this occasion to recommend this sale to the attention of agriculturists. The character and importance of the cattle and sheep of the late Mr. Meade, have frequently been a subject of remark in the American Farmer. This stock is the result of the untiring perseverance, good judgment and ardent patriotism, of the late proprietor, and comprises a very extensive collection, making attendance at the sale, an object worthy of the consideration of every farmer who wishes to improve or add to his stock.

AMERICAN FARMER.—This work has commenced the fifteenth volume, having run thus far, a race of real usefulness, dispensing every week, matter of great interest to the farmer and practical man. It was commenced in Baltimore by J. S. Skinner, Esq. of that city, and we well remember the curiosity which was excited by a paper bearing so novel a title. "American Farmer," said an old fellow with a frock on: "what won't they get a going next!" What is it said a bystander? what is it? "why a thing to coax us farmers to vote them into office I s'pose." But they were mistaken, it has pursued the "even tenor of its way," without meddling with party, or stirring up sectional jealousies. It has been a successful pioneer, and fearlessly led the way in the march of agricultural improvement; and we hope centuries will roll away, ere it shall diminish in interest, or cease from its labors. We wish we could persuade some of our friends, who take at least a half dozen political FIREBRANDS to drop one of them and take the American Farmer—to drop another and take the New England Farmer, (our own hebdomadal they take of course) they would then have something which their great grandchildren would delight to read, and three party oracles to boot, and they would be enough to keep one neighborhood in a feud.

[Maine Farmer.]

HORTICULTURAL SOCIETY.—At the stated meeting of the Society for the present month, several members exhibited plants or other objects of horticultural interest. A notice of some of them is annexed:

The finest plant exhibited was a really splendid specimen of Azalia, (the Phenicea of Loddiges) in full flower. The bush was upwards of three feet high, well branched from the earth upwards, and covered with a profusion of delicately tinted purple blossoms, each about two inches in diameter. It was certainly well calculated to furnish additional proof, (were any such necessary) of the reward which a careful culture of the Azalia will afford the amateur. The species in question is undoubtedly a very fine one, and when contrasted with the scarlet and white flowered kinds, the effect produced by the varied hues of their intermingled blossoms, whether in the parlor or the conservatory, is quite enchanting—Exhibited by Mr. KURTZ.

Two specimens from South America were sent by Dr. COHEN to the Society. One the fruit of a Palm tree, supposed a species of Caryocar. The other a most singular production, bristled on every side with enormous spines of most repulsive appearance. It is a dried portion of the stem of a Cereus, supposed to be true *Spinosisimus*. At all events, its claim to at

least a similar appellation cannot be disputed. Both these were reserved for the Museum of the Society.

ZEBULON WATERS, Esq. presented a most charming production discovered by him last spring in a wild state in the neighborhood of this city—the double flowered Wood Anemone, (*Anemone Thalictroides*.) The single variety is quite plentiful in our woods, but the double one is very rare. It is well worthy of cultivation, and the delicate beauty of its rose tinted blossoms, will amply repay whatever trouble may be taken with it.

Two roses, exhibited by Mr. SAM'L. FEAST, excited general interest. They are quite new varieties, raised by him from seeds. One was obtained from seeds of the common tea rose, very probably with an admixture of some other variety. The appearance of the plant and its foliage, is particularly neat; it grows very freely, and flowers beautifully. Blossoms large, and well colored, borne on graceful stems, with a singular fragrance, like that of the common tea rose and the China rose combined. It has been named, in compliment to an amateur of the city, Kurtz's Rose, or *Rosa Thea*, var. *Kurtzii*.

The other rose, likewise obtained from seed by Mr. Feast, is the most curious rose perhaps ever produced. It is a dwarf, and so completely does it vindicate its title to that appellation that although it has now reached the termination of its third year, the bush is not yet quite *two inches* in height! It is a sturdy little affair, well furnished with branches and clothed with leaves of surprising neatness. The blossoms are quite as extraordinary; they are double, of a beautiful color and very well formed, of a little more than half the diameter of a five cent piece! It is a real *bijou*, and has been named Master Burke, having flowered for the first time, during the period when the young Roscius was performing here on his first engagement.

We learn that a special meeting of the Society will be held on Saturday next, when the members are again expected to exhibit specimens.—*American*.

PECULIAR METHOD OF TURNING WOOL INTO FUR. The wool growers of Podolia and the Ukraine, and also in the Asiatic province of Astrachan, have a peculiar method of turning wool into fur. The lamb, after a fortnight's growth, is taken from the ewe, nourished with milk and the best herbage, and wrapped up as tight as possible in a linen covering, which is daily moistened with warm water, and is occasionally enlarged as the animal increases in size. In this manner the wool becomes soft and curly, and is by degrees changed into shining beautiful locks. This is the kind of fur which passes under the name of Astrachan, and is considered on the continent as the most genteel lining in winter cloaks. Similar trials with German sheep have been attended with the same success. The Saxon breed of sheep have, within the last ten years, superseded the merinos, and their wool is of superior quality.

FOREIGN MARKETS.

LIVERPOOL, March 7.

Nothing especial has occurred in our market this week, except perhaps that we have had a good demand for cotton, sales large (but more particularly in Brazil, which are 1d higher in several descriptions) and a better feeling on the whole prevailing. In American cotton no change has taken place in prices.

Naval stores are dropping, both tar and turpentine. In other articles we have scarcely any thing of importance to report.

Sales March 4th.—There has been an extensive demand in the cotton market to-day, and the transactions are estimated at 3500 Bahias at 7 5/8 d, and Maranhans 5 5/8 to 91, and in American descriptions 2500 bales from 64 to 81d.

AGRICULTURE.

(From Proceedings of the N. Y. State Agricul. Society.)

ON THE USE OF LIME IN AGRICULTURE.

Westchester, Penn. December 17, 1852.

DEAR SIR.—Your letter, containing a number of queries relative to the operation and utility of lime, in the process of agriculture, was received in the early part of June last; but as I have been much engaged, during the past summer, with duties which required all my attention,—and, as your letter intimated that answers furnished “any time during the present year” would be in season for your purposes.—I have taken the liberty to postpone my reply until now.

I proceed, then, with great pleasure, to furnish you with such facts and remarks as my opportunities for observation have enabled me to offer. With a view to render the answers more explicit and satisfactory, I will annex them, *seriatim*, to your several inquiries.

Query I. “Upon what lands does lime operate most beneficially?”

1. In regard to geological formation.—as primitive, transition, secondary, and alluvial?
2. In reference to the soil,—as sand, clay, lime and vegetable matter?
3. As indicated by natural growth of timber and plants?

Answer. My residence has always been in a primitive region, and my observations very much limited to agricultural processes in soils upon that formation. The prevailing rock here is gneiss,—with occasional beds, or veins, of hornblende, greenstone and scinite. About five miles to the north of us, is the great valley of transition limestone, stretching from northeast to southwest; and immediately on the southern side of this valley, running parallel with it, is a broken ridge of hills, formed of mica slate,—with beds of serpentine rock and hornblende, on the side next to the gneiss rock, on the southeast. Over the gneiss rock, and among the hornblende, the soil is generally a stiff loam; and there, I think, the best effects are perceptible from a given quantity of lime. On the soil overlaying the schistose rocks, the good effects of lime are sufficiently obvious, under the management of skilful farmers; but the benefits seem to be less permanent. On the serpentine rock the soil is extremely sterile,—and neither lime nor barnyard manure can be used with much advantage. In the limestone soil of the great valley, where one would suppose it was already redundant, lime is used with advantage; and much heavier dressings are put on, than in the adjacent districts. I cannot furnish the rationale of this practice; but I believe the fact is established, that more lime is required to produce the same beneficial effect upon soils resting on limestone rock, than upon those overlaying gneiss,—and perhaps some other primitive rocks.

I have had no opportunity to witness the effect of lime upon secondary, and strictly alluvial, formations; but the above circumstance has led me to suspect, that the same quantity of lime would not be so signally beneficial in secondary, as it is in certain primitive formations.

Lime, undoubtedly, has a good effect in soils which are sandy,—even where sand predominates; but I believe its meliorating properties are most conspicuous in a clay soil,—or rather in a stiff loam. A good proportion of decomposed vegetable matter adds greatly to the beneficial effects of lime; and hence our farmers are desirous to mingle as much barnyard manure as possible with their lime dressings,—and to get their fields into what is called a good sod, or turf,—full of grass roots. Then a dressing of lime has an admirable effect. The soils indicated by a natural

growth of black oak, (*Quercus tinctoria*), walnut (*Juglans nigra*), and poplar (*Liriodendron*),—and those in which such grasses as the *poas* and *festuacs* best flourish, are generally most signally benefited by the use of lime. In short, I may observe, that lime has been found more or less beneficial in every description of soil, in this district. It is most so, on hilly, or rolling lands, where clay predominates,—less permanently so, among the mica slate,—and least of all, on the magnesian rocks. The soil on these last is rarely worth cultivating.

Query II. “What quantity of lime is applied to the acre, upon different soils, at a single dressing, and during a period of years?”

Answer. The quantity of lime, per acre, which can be used advantageously, varies with the condition and original character of the soil. Highly improved land will bear a heavier dressing than poor land. On a soil of medium condition, the usual dressing is 40 to 50 bushels per acre. A deep, rich soil, or limestone land in the great valley, will receive 70 to 80 (and I am told even 100) bushels to the acre, with advantage. On very poor land, 20 to 30 bushels per acre, is deemed most advantageous to commence with. It is usually repeated every five or six years—i. e. every time the field comes in turn to be broken up with the plough; and as the land improves, the quantity of lime is increased. The prevailing practice here, is, to plough down the sod, or lay, in the fall or early in the spring,—harrow it once,—and then spread the lime (previously slaked to a powder) preparatory to planting the field with Indian corn. Every field, in rotation, receives this kind of dressing; and as our farms are mostly divided into about half a dozen fields, the dressing of course comes once in six years, more or less according to the number of the fields. Some enterprising farmers, however, give their fields an intermediate dressing, on the sod, after they come into grass; which I consider an excellent practice,—tending rapidly to improve the condition of the land.

Query III. “Is it applied in a caustic or an effete state?”

Answer. It is usually obtained in a caustic state from the kiln,—deposited in heaps in the field where it is to be spread, and water sufficient to slake it to a powder, is then thrown upon it. As soon as slaked, it is loaded into carts, and men with shovels distribute it as equally as possible over the ground. It is generally considered best to put it on the ground whilst it is fresh, or warm, as the phrase is; and it is certainly easier to spread it equally, while in a light pulverised state, than after it gets much wet with rains. I am inclined to think, too, it is better for the land, when applied fresh from the kiln.

Query IV. “To what crops is it most advantageously applied, and at what seasons?”

Answer. It is usually applied, as already intimated, to the crop of Indian corn, in the spring of the year—say the month of April. Occasionally it is applied, preparatory to sowing wheat, in autumn. When used as a top dressing, on the sod, it is generally applied in the fall—say November. The prevailing impression is, that it is most advantageously applied to the Indian corn crop; and hence the general practice. But the truth is, it is highly advantageous at any, and at all seasons; and our shrewd old farmers have a saying,—“Get your lime on for your corn, if you can,—but be sure you get it on the land, some time in the year.”

Query V. “How is it incorporated with the soil—by the plough or the harrow? and is it applied in any case as a top dressing to grass and to grains, and with what effect?”

grain on the inverted sod,—and, the ensuing spring, to manure the same field for a barley crop;—or, to reserve the manure until the succeeding autumn, and apply it to the wheat crop. It is not well settled which of these is the better practice. Each has its advocates; but it is most usual to reserve the manure for the wheat.

Answer. As already stated, after the sod is ploughed down for Indian corn, it is usually harrowed once, to render the surface more uniform. The lime is spread as equally as possible over the field,—and then the ground is well harrowed in different directions, in order to incorporate the lime with the soil. Soon afterwards, the field is marked out, and planted with corn. The plough is rarely, if ever used, for the purpose alluded to. I have mentioned above, that lime is occasionally used as a top dressing, for grass. It appears to be particularly beneficial to that crop; and answers extremely well, when applied in that manner. The practice of applying it to Indian corn, as above related, is, however, chiefly followed; and the application of a dressing to each field, in rotation, causes as much labor and expense every year, as our farmers generally are willing to incur. Lime has rarely been used as a top dressing to grain crops, within my knowledge.

Query VI. “What is the ordinary cost, per acre, of liming, and the relative profits, in increased products, of a period of years?”

Answer. Quick lime, at the kilns, usually costs twelve and a half cents per bushel. The farmers generally haul it with their own teams; and the additional expense depends, of course, materially upon the distance. It is frequently hauled by them a distance of 8, 10, and even 12 miles. The average, perhaps, is about 5 or 6 miles. It is delivered to me by the lime burners, (a distance of near 6 miles,) at 18 cents per bushel. At the rate of 40 bushels to the acre, the cost, at 18 cents, would be \$7.20 cts. per acre. It is difficult to estimate, with precision, the relative profits, in increased products: But I can safely say, from my own experience, on a small farm of middling quality, that two dressings of lime at the at the above rate, in the course of 8 or 9 years have more than trebled the products of the land to which it was applied, both in grain and grass. It is to be understood, however, that the system of ploughing only so much ground as could be well manured, was adopted at the same time. I may also observe, generally, that the farmers of this district, (who are shrewd economists,) are so well convinced of the beneficial effects of liming, that, costly as its application seems to be, they are unanimous in sparing no effort to procure it. Lime has been found to be peculiarly favorable to the growth of pasture, when the farm is otherwise well managed; and, as our farmers are mostly in the practice of feeding cattle, they resort to liming as an indispensable auxiliary to successful grazing.

Query VII. “Is lime applied with yard manures, or earthy composts, and with what results?”

Answer. I have already intimated that vegetable matters, and especially yard manures, are highly important in conjunction with lime. Both are valuable, even when used separately; but when combined, the effect is most complete. It to this be added, that great secret of good farming, viz: to plough only so much ground as can be well manured,—the state of agriculture may be considered nearly perfect.

Lime is, in some instances, added to earthy composts, preparatory to distribution on the field: But it is doubtful whether the extra labor of this method is compensated by any peculiar advantages. It is not generally practised.

Query VIII. “Is powdered limestone (carbonate of lime) applied to soils; and if so, does it induce fertility otherwise than by mechanically ameliorating their texture?”

Answer. No instance of powdered limestone being applied to soils has come under my notice. I can, therefore, form but a very imperfect opinion of its utility. If it were even as beneficial as quick lime, (which I doubt,) I apprehend it could not be procured and applied with less cost and labor.

Query IX. “On what soils, if any, in your neighborhood, is lime found to be inoperative, as a fertilizing application; and the cause of its failure?”

* The yard manure is not usually mingled with the lime, when the latter is first applied. The practice is, to lime the Indian corn ground, prior to planting that

Answer. There is no soil in this district, deemed worthy of cultivation, on which lime is *wholly* inoperative as a fertilizer. On some sterile, slaty ridges, and on magnesian rocks, it has indeed but a slight effect; and even the benefits of barnyard manure are very transient. In low, swampy grounds, also, unless they are previously well drained, the labor of applying lime is pretty much thrown away. There seems to be something in the constitution of magnesian rocks peculiarly unfriendly to the growth of the more valuable plants. Indeed, there are patches of the soil perfectly destitute of all vegetation. Repeated attempts have been made to cultivate the bases of our serpentine banks; but neither lime, nor manure, will enable the farmer to obtain more than a light crop of small grain. Neither clover, nor the valuable grasses can be induced to take root and flourish in the ungenial soil. It is, therefore, almost universally neglected.

I have thus endeavored, (in rather a desultory manner, I confess,) to answer your queries according to my best judgment. If what I have furnished shall in any degree tend to make the subject better understood, I shall be amply gratified. With great respect, I have the honor to be, your obedient servant,

WM. DARLINGTON.

JESSE BULL, Esq. Cor. Sec. &c.

(From the Virginia Farmer.)

CULTURE OF CORN.

Indian Creek, Feb. 1, 1833.

DEAR SIR,—In the last number of the Virginia Farmer, it is stated that, a Mr. Megginson of Buckingham, made last year, from one acre of land, one hundred and eight and a half bushels of Indian corn. That was certainly a great product, and shews conclusively the value of manure; and surely ought to stimulate every farmer to use all means in his power to raise as much of that indispensable article towards good and profitable farming, as are within his reach. I have read Mr. Megginson's letter inserted in your paper, wherein he states his manner of preparing land for corn, and the subsequent cultivation. This gentleman is certainly a practical farmer, whose examples (in general, as far as they are developed by his letter,) are worthy of imitation. Under a hope that others of more experience than myself may be induced to give us their lights on the subject of agriculture—I beg leave to state the manner that I prepare my corn land, and the mode of cultivation afterwards. I commence on or about the first of November to follow with a two horse McCormick plough, (the best kind I ever saw, and I believe the best I ever shall see,) ploughing about five inches deep. The last of March I bed my land five feet, with three furrows, and crop it three feet apart, and commence planting as soon afterwards as I can, allowing the plough or ploughs that are cropping sufficient time to keep ahead of the planters; of course I plant my corn five feet by three, putting three grains in the hill, or rather the hole. If the spring is tolerably favorable, the corn will be large enough to thin out one stalk about the 20th of May:—About this time I put in the cultivator, made in a triangular form, having in it four hoes and one tooth, the latter is fixed in the hinder end of the right side; the advantage of the tooth is found in running immediately along side of the young corn without covering it, by throwing dirt on it, two strokes of this cultivator are sufficient in a row. As soon as I get over my crop the wide way (as we call it) I take the tooth out of the cultivator and put a hoe in its place and commence cropping the narrow way; the corn is then large enough to bear the little dirt that is thrown to it by the cultivator. My object in crossing, is to break and pulverize the bed, and level the ground. After the crop is passed over in this way, which is speedily done, one stroke being sufficient, I cross no more and continue to work the corn with the cultivator alone, until a short time

before harvest, when I put in a one horse plough, and run two furrows on each side of the corn, throwing the earth up pretty well to the corn, the cultivator will at one furrow cut out that which is unploughed in the middle. I omitted to state that, I commence hoeing my corn or rather chopping around it when I first start the cultivator, taking out one stalk if there are three, thereby thinning the corn gradually. The ploughing is intended to facilitate and lessen the hoe work the second hoeing and prevent the grass from getting a hold during harvest; a time when we have to take all our hands out of the corn field. After harvest the cultivator is again used, and nothing else except the hoe. I think Mr. Megginson is mistaken in saying that corn ought not to be worked after it begins to joint; I know by several years' experience, that corn ought to be harrowed or stirred with a cultivator (the latter I prefer) until the first of August. I am under the impression that he plants his corn too thick, unless in a very highly improved land. It is true he will have more ears, but I doubt very much if more bushels would not be made by planting five and three, one stalk, unless the land is rich enough to produce ten or twelve barrels to the acre, then two stalks may be safely left. One cultivator will do as much work in a day as two, or perhaps three ploughs, and according to the foregoing mode of cultivating a corn crop, much is saved, less team is necessary, fewer hands will be required, and the crop cultivated in a manner neater and better calculated to insure a good crop. If you have none of McCormick's ploughs in your county, I would earnestly press you to get one, No. 10. You can get them in Fredericksburg and perhaps in Richmond. I have thus roughly given you my mode of cultivating a corn crop: there is nothing in it theoretical, and I am confident that it is the safest mode in this part of Virginia, at least to insure a good crop. If you think any good may be done by the above (except filling up a place in your paper) you can use them as you please.

Yours,

RALPH EDMOND.

(From the Genesee Farmer.)

INDIAN CORN.

Greatfield, 2 mo. 1, 1833.

In the chapter on Indian corn, (*Zea mays*.) in the Library of Entertaining Knowledge, it is said, "Of this plant only one species is known, but there are several varieties." It would be hard to determine whether the writer meant to include the Valparaiso corn among these varieties, or whether he meant to exclude it entirely as an Indian corn. Either case would be incorrect. The Valparaiso or cross corn, constitutes another species of *Zea*, named *Z. curagua*, distinguished by its serrated leaves; and the grain when roasted splits regularly into the form of a cross. It is represented as a smaller species, and was introduced into Britain in 1824.

It is also said, "American Indian corn is the largest known variety of maize. It is found growing wild in many of the West Indian islands as well as in the central parts of America. It will rarely come to maturity in northern climates; and could never be securely relied on as a crop in any part of Europe."† All this may be true, and yet by not telling the whole truth, it leads on directly to error. The small variety found with the Indians by the first settlers of New England soon after they landed at Plymouth, was as decidedly an American variety as that which grew in the West Indies. This same remark will apply to the variety cultivated by the Mandans on the Missouri; and which ripens, according to Nuttall, in a climate where no other variety could exist.

It is further said, "In the Mexican states its productiveness is calculated to excite wonder, if not to provoke incredulity on the part of European agriculturists. Some particularly favored spots have

been known to yield an increase of eight hundred for one."* Much of the wonder and incredulity would abate however if the same facts were stated in a different manner. Comparing this crop with that of wheat, or of other kinds of grain commonly cultivated in Europe, the product seems enormous; for if we say one bushel of wheat will seed an acre, and one acre will produce forty bushels, the increase is only one-twentieth part of the Mexican crop, and a vague idea of some eight hundred bushels to the acre is presented. But when we inquire how much Indian corn have they to the acre? and then learn that it may not greatly exceed one hundred bushels, we come to understand it differently, having discovered that more is owing to the small quantity of seed corn required, than to the magnitude of the crop.

By good culture, as great a return may be had from many spots within the 44th degree of north latitude. The ears of the most common variety of Indian corn cultivated in the Genesee country, will average nearly ten inches in length, with eight or ten rows, each containing fifty grains; and consequently each ear contains four hundred or five hundred grains. Now a stalk of Indian corn in a fertile soil with good tillage and room enough will produce at least two ears, and the yield will be from eight hundred to one thousand for one. If we take the quantity usually planted in our fields, however, and compare it with our greatest crops, the proportionate yield will be greatly reduced; for it is held the best policy to use plenty of seed to guard against accidents, or the depredations of animals; and a vacancy is more to be feared than a surplusage, although each stalk will be less productive.

In speaking therefore of eight hundred to one, we know not whether the yield is great or moderate, for one plant treated in the best manner in a rich soil may produce more than two thousand to one, even when the yield, averaging the whole field together, is not fifty bushels to the acre.

"In the United States of America," says the same author, "the Indians—these simple and untought people, discovered and practiced a method of preserving their grain after harvest which afforded a certain protection against the ravages of insects. Their method was to separate the corn from the cobb [cob] as soon as the harvest was finished: to dry it thoroughly by exposure to the sun, and to a current of air; and then to deposit it in holes dug out of the earth in dry situations, lining these holes with mats of dried grass, and covering them with earth, so as completely to prevent the access of air."‡

The United States of America is a vast country, comprising a great many Indian nations, differing in manners as well as language; and therefore in speaking of their peculiarities, it is always safer and more satisfactory to name the nation in which such customs prevail. The only account which I recollect, of the Indian mode of storing their corn, is contained in the history of the first settlers of Massachusetts. An exploring party "discovered hillocks of raised earth" which they conjectured to be the graves of the Indians; but on opening one, to their great surprise, they found it to contain Indian corn which was "still in the ear." In this part of the United States it is commonly kept in the ears through the winter. Instead of excluding the air, corn cribs are constructed so as to admit as much of it as possible. We know of no insect that attacks Indian corn after it is ripe and husked.

Some farmers have said that *topping* and *blading* hastened the ripening of Indian corn; and this author supposes the operation also "affords more nutriment to the grain;" but I do not discover how the entire removal of one half the plant could produce any such effect.

The practice in some districts may have induced him to believe that the ears when ripe "must be

plucked off together with the husks and conveyed all once in carts to the barn." There is no necessity for this practice, and accordingly it is local. It is commonly held to be a saving of labor to husk it on the stalk, whether the stalks are cut and stacked, or whether they are left standing in the field. D. T.

(From the New England Farmer.)

SELECTION OF SEEDS, IMPROVED VEGETABLES, &c.

Camden, N. J. 3d month, 1, 1833.

Respected Friend,—I observed in the N. E. Farmer, under the head Agricultural Essays, on the subject of seeds, the author says, "seeds not natural to the climate degenerate and should be changed annually," and, "that corn, barley, oats, and seeds of all kinds should be changed every year, it will pay the farmer four-fold for the trouble of doing it." This is a subject of great importance to the agriculturist, and should be fully investigated from actual experiment before it is implicitly adopted, as it is attended with much trouble and expense, in making these repeated changes. I believe some benefit may result from making changes and introducing a greater variety of sorts, and when we find good and productive kinds, of either vegetables or grain we had better endeavor to continue to improve them ourselves by proper care and cultivation and saving of the best for seed than depend upon our neighbor's care. I, however, can speak from about forty years of observation and experience, that seeds not natural to our climate, instead of "degenerating" by care and proper cultivation have a tendency naturally to become more acclimated to our climate, and instead of making these annual changes it would be better for the farmer to endeavor to improve these good sorts than to be annually changing with his neighbors.

I expect it will be admitted that much has been effected in the improvement of the breeds of cattle and sheep, sometimes by a cross and again by selecting the most perfect in form and size, and raising a stock from the best milkers, for instance the Shorthorn Durham, and Alderney breed, also Bakewell's celebrated sheep, these have all been derived from crosses, and selecting the most perfect. The same course I think will be found to produce the same beneficial results of mixing some kinds of seeds of the same species and improve from the best. I will now give an instance of a trial made by one of my ancestors more than sixty years ago; he planted some of the small kind of chicken corn (or as the children call it pop corn, from its bursting so handsomely when roasted on a shovel over the fire) which usually produces from four to eight ears on a stalk, with the common large Indian corn, and improved from that mixture, for a few years, until he got what he thought a good and perfect kind. This small sort was also very productive in leaves as well as in ears, which is of great importance as regards fodder, as some of our kinds produce but few leaves and are not worth much for that purpose. The product of this mixture is, generally, from two to four and sometimes six ears to a stalk. This same kind of corn has been annually grown on the same farm since that period without any other mixture, and to this time the usual product is from fifty to seventy-five bushels per acre. On the same farm and about that period and by the same person the like results took place with squashes; they are still grown there, and do not degenerate either in flavor or quantity.

About twenty years since, dining with a friend of mine about 80 miles from my home, I observed some potatoes brought on the table. I was struck with their unusual white appearance, and their flavor was also excellent (at that time we rarely saw any but what were of a yellow appearance.) On inquiry I found he had procured them from Long Island, about

two years before. They had been recently brought from England, and were called Foxites or Fox's seedlings. I obtained a few and planted them, and have continued to do so, from that period to the present time without any change with my neighbors, they continue to be as good in quality and as productive in quantity, but I am always careful not to make use of the best for cooking or sale and plant the refuse. When this is done I do not marvel at the common complaint of seeds degenerating. It is a good practice and should be done every few years, to be careful when the potato crop is gathering, when a large number of good sized fair potatoes are found attached to a stalk to put them by and plant them separately for seed. I think it of importance for farmers not too hastily to adopt theory without being tested by actual experiment, by annually changing their seeds. I have found from an experience of nearly forty years a benefit from my practice of saving all kinds of seeds designed to plant, to make the selection from the best and most productive. This rule will apply to rye or wheat as well as all other seeds. The rye I now have, is the product (many years since) from a remarkably large seed, and the grain much whiter than common, and it is now generally sown in this neighborhood. Indian corn of any kind can be improved. It is my usual practice to go through the field previous to gathering the crop, and make the selection from the best shaped stalk with the most leaves and most productive in ears, attending also to the time of ripening, and by sowing some of the most early we can improve as to the time of ripening. By taking this care with our early pease we get them much earlier for market than formerly. I wish our farmers, more generally, would try the experiment for themselves of making a careful selection of seeds endeavoring to improve the kinds, and I think they would find as proportionate a benefit from it as they do from raising stock from the best cattle.

Respectfully, thy friend, BENJAMIN COOPER.

HORTICULTURE.

(From the New York Farmer.)

IMPORTANCE OF THE APPLE.—DIRECTIONS FOR THE MANAGEMENT OF THE ORCHARD.

Mr. Editor,—During a residence of some few months in this country, your interesting journal has frequently fallen into my hands; and as I perceive that you occasionally devote a portion of it to the dissemination of agricultural information, I have determined, if it meets your approbation, to contribute the result of my observations through the medium of the same. I am a citizen of the world, and have had frequent opportunities of comparing the state of agriculture in different parts of it, but I have never met with a place so eminently adapted to farming purposes as Long Island. I have no doubt the system pursued by your farmers is, in general, best adapted to their interests; for I have noticed, during my peregrinations, that the capabilities of a country are best known to the inhabitants,—that is to say, I believe that a man will soon find out from half a dozen different crops the one which is best adapted to his soil, and will produce the most money. But there is one crop which, under proper management, can be made more productive than any your farmers cultivate, and which, as my observation has extended, has received very little attention—I mean the apple. It would almost be questioning the good sense of your farmers, in this age of general intelligence, to ask them if they did not know that this country is the most favorable on the globe for the culture of this fruit; and yet it really appears they know nothing of the matter. I am told that the celebrated Newtown pippin originated on Long Island, and I know it is thought to combine more good qualities than any apple ever cultivated; many of these trees are annually imported into

Europe, but none of them produce fruit equal to that from under the genial influence of your sun; the fruit itself is imported in considerable quantities, and it is no uncommon thing to see placards of "Newtown pippins" posted in the confectioners' windows as you pass through the streets of London; it sells at a very high price, frequently as high as six or eight cents for a single apple. With a knowledge of these facts, the cultivation of this admirable fruit should become an object of primary importance.

Now, it has been satisfactorily proved that, with proper care in trimming and manuring, together with a judicious selection of the stocks (a matter of all importance) six or at most eight years are time enough for trees to attain sufficient maturity to produce in three years as much as will pay all the expenses attendant upon their culture; that is to say, by the time they are eleven years old they will have paid for themselves; after this period they are rapidly becoming more productive, and require less attention as they increase in size, providing they have been properly trimmed every year, and manured at least every other year, till they begin to produce plentifully. By this time they will have become sufficiently established to draw their nourishment from the surrounding soil, and the manure bestowed upon the undergrowth. But your farmers tell me their orchards will not grow so fast; they say it requires twenty years for them to attain a full bearing state. This is true, and I will tell you the reason: they have been so long accustomed to consider them unprofitable, that what little attention they bestow (if perchance they should think them worth any) is given unwillingly, and with no idea of reimbursement. The consequence of this is that the farmer, instead of assigning a suitable time and attention to his orchards with as much care as the rest of his farm, takes some odd moment, whether suitable or otherwise, gives them a superficial trimming or rather mangling, and thus leaves them, without any protection from the weather, which immediately commences its depredations upon the tree, and in a few years it is either completely destroyed, or becomes so diseased by the rot and canker, (both produced by the hacking system,) as to become a mere incumbrance, so that the Indian corn or potatoes, which might grow where it stands, would be worth ten times as much as its fruit. The great importance of applying some kind of dressing to trees after trimming appears to be almost entirely overlooked. What would be thought of a surgeon who should amputate a limb, and leave the bleeding stump exposed without any protection from injury, or any application to prevent the atmospheric influence upon the grievous wound he had inflicted?

Now, it is almost as preposterous to suppose the one would, under such circumstances, do as well as the other. In either case, no reasonable man will doubt the utility of some protection, in order to allow the healing process to go on uninterruptedly. With regard to the nature of the application, it is of little consequence what it is composed of, provided it is not of an acrid character. I have found, by experience, that a composition of equal parts of fresh cowdung and common clay answers the purpose admirably. It forms a most tenacious plaster, and resists the influence of the sun and rain, which is the only object in view; it has this advantage over most others, it costs nothing, and can always be had. I have tried most of the applications recommended in books and papers—Forsyth's among the rest; they are all good, provided they will stand the weather. None of their component parts are received into the circulating juices of the tree; the only object in applying them is to prevent the pernicious influence of the sun and rain, together with those drying winds which cause the extremities of the limbs to crack open and afford admission to moisture; whilst in consequence of the exposure to the sun, the sap which exudes, and is intended by nature to heal the wound, evaporates, and leaves the tree without any means of effecting a

cure. This evil is also produced by suffering two grafts to grow upon the same stock: even if there should be two separate branches and a handsome bifurcation which it would grieve you to destroy, nevertheless, you should either cut off one (the most horizontal one of course,) and graft the other, or if the stock will admit of it, cut and graft below both. This has frequently been told, and it is surprising it is not always practised. Turn your eye to the next orchard, and if you do not see one example of this pernicious practice, take my word for it, the man knew how to graft his trees. The philosophy of the thing is as plain as a pike-staff: if you leave both grafts, you impose upon good nature; you literally want two trees to grow where nature meant there should be but one, which one will prove a handsomer more durable, and fruitful tree (aye, and a larger one too, if size is your object) than if you had left both. For the same reason that I recommend removing one graft, I would urge the importance of beginning to trim early. Begin as soon as the graft expands. If one bud should show a disposition to outgrow the others, rub all off but that one—it will grow the faster, you will lose nothing by it, as it will, nine times out of ten, exhaust the others so completely as to become the leading shoot, and will throw out lateral branches enough to form a handsome head without their assistance.

The graft should always be secured by tying a long stick round the stock, suffering it to project two feet above the graft to which it should be tied as fast as it grows. This rubbing off the buds is the first year's trimming; the next you can select the most promising shoots, and those which spread handsomely, cutting off the others with a sharp knife—every shoot you cut off affords additional nourishment to those which remain—an immense deal of labor is thus saved by *beginning to trim early*; it is much easier to cut off a limb with a penknife than an axe—besides this, you can see much better which it is proper to remove; you can make your tree spread beautifully; and thus, what would after six or seven years of neglect require a week to perform, may be done before breakfast, and become a pleasing employment in the one case—a task in the other. You should take care to prevent the access of the rain to the cleft which is made for the graft, as it would prove very injurious. In order to do this with little trouble, when you set your grafts, instead of the ordinary daubing with clay, use a composition of equal parts of wax and tallow, this will keep out the weather, and will not melt in the heat of summer. I have known it to remain upon the tree four years as good as when first applied; it is much more convenient than mud, and will be found an excellent preparation—the addition of a little rosin will make it more tenacious—that of ochre, as lately recommended, is certainly of no kind of use. If the bark of your trees appears unthrifty or infested with insects, apply soft soap, the alkali kills the insects and causes the bark to assume an uncommonly vigorous appearance. I shall enumerate a few more errors which cannot fail to strike the most unobservant beholder—planting too near, grafting too low, and suffering the grass to grow round the roots of young trees. By planting too near you deprive your trees of free access to the sun, this spoils the fruit as well as the crop which grows, or rather tries to grow, beneath them. It makes little difference to a man who has a hundred acres of land whether his orchard occupies four, six, or eight acres; indeed, if trees are planted 60 feet apart—and I would never have them nearer—it is doubtful if they would make any perceptible difference in the crop; if this be true, where is the necessity of planting them 20 feet apart, thereby spoiling trees, crop and all; it is certainly the best policy to plant six acres with the same number of trees that are commonly planted upon four. In the next place, graft them ten feet high, so that your ploughman can drive under without knocking his hat off; the advantages and disadvantages attending this

practice are the same as those in planting too near. Suffering the grass to grow round the roots of young trees is an evil of prominent magnitude, and I will venture to say causes the destruction of more young orchards than all the others together. Those who pretend to any solicitude about their orchards, say that the ploughing and manuring for the undergrowth is all that is requisite for the trees; but even if this would, under ordinary circumstances be sufficient, they forget that they are usually grafted so low that the plough cannot get near them. There is nothing like actual demonstration and comparison. Let any man select half a dozen trees in his orchard, give them a wheelbarrow load of manure, and then fall to and dig it in honestly and fairly, and compare the produce with six of the others, there is no doubt he would be pleased with the result. But I have trespassed long enough on the patience of you, Mr. Editor, as well as your readers, and will only add one good old maxim that I used to read in my youthful days, "whatever is worth doing at all, is worth doing well, and it is impossible to do any thing well without attention."

Part of the above remarks were published several years ago in one of your neighboring publications, and I now communicate them for your interesting Magazine.

E. H. D.

(From the Library of Agricultural and Horticultural Knowledge.)

ORCHARD IN MINIATURE.

An Orchard in Miniature, as proposed by a correspondent in the *Gardener's Magazine*, may, where space is an object, be adopted with advantage. "By planting the proper sorts, apples may be grown on as small a space of ground as gooseberries; and a small or large square, according to the size of families, appropriated to apples, will grow every year enough to supply their wants. I am not vain enough to think that I am alone in growing them in this way, as I should think horticultural economy would prompt many besides myself to gratify their eyes, their pockets, and their appetites in so easy a way. I have my ground a strong clay mold, trenched two feet deep, in December; as soon as it is settled, say a fortnight after trenching, taking advantage of a frosty morning, the holes are opened and left for the frost to mellow. February is the best month for planting on heavy ground; by that time the earth taken from the holes will be in a fine pulverized state. The holes need not be very large; two feet over, and one and a half deep, will be enough; with some rich soils there will be no occasion for trenching; but then the holes must be larger, say three feet over, and two feet deep; the plants must be six feet apart every way; I arrange mine in quincunx. With a six feet measuring stick this is done with scarcely any trouble. I really do not know any sight more pleasing to a domestic mind (or what fruit contributes more to our comfort than the apple?) than this orchard in miniature, when covered with bloom, and again when laden with fruit, as they seldom miss bearing in abundance.

This plan will not extend to the strong-growing sorts, as they are not easily kept within bounds; but the following six, will amply repay the trouble and trifling expense of planting. I have placed them in the order of their ripening:—Mank's codlin, Hawthornden, Kerry pippin, Downtown's pippin, Christie's pippin, and the old golden pippin. The trees must be chosen with stems not exceeding one foot six inches in height. In September I look over the trees, take off superfluous wood, and shorten the long shoots; this strengthens the bloom buds, which are formed abundantly upon the young wood of all the sorts named. Of course in doing this, an eye must be had to the formation of the trees, which ought to be gradually brought into a handsome round bush. For the first five years a row of strawberries may be grown, between each row of apples, or any other dwarf light crop; but strawberries are most in keep-

ing, a word, which, in every gardening operation ought not be lost sight of. Let me add—they ought to be worked on Paradise stocks, or the small wild crab (mine are on the last) not by any means on the free stock raised from apple pips, the very worst that can be used.

(From the Genesee Farmer.)

AQUATIC PLANTS.

For the benefit of such horticulturists as have in their gardens a small but durable stream, I copy the following paragraphs from the letter of a botanical friend, which I received a few months ago. Many of our sub-aquatic plants are of great beauty; and some of them will grow in a prepared soil remote from water; but others like true aquatics, can only be successfully cultivated where there is a perennial fountain to supply their wants.

"I lately saw the *Sarracenia purpurea* growing very finely in a garden. It was taken from a swamp, and planted in a moist soil close to a small but constant stream. I mention it, because it is sure to dwindle and perish in common earth.

"Oh! I have seen the *Cyanus luteus* in flower. It is really one of the finest plants I ever saw: the flowers are from three to five inches in diameter, and if they were opened out, would measure seven or eight inches across. When fresh, their fragrance to me is very grateful. It should be cultivated wherever it can be got to grow; it requires a small pond of water two or three feet deep with a muddy bottom.

"There is in this neighborhood a *Sagittaria* with double flowers that is said to be splendid, but I have not yet seen it.—P. S. A friend has just handed me a bunch of the double *Sagittaria*, and it is a curiosity worth trying to get."

There are many subscribers to the Genesee Farmer, horticulturists, who have, or who may have, fountains or durable streams in their gardens; and who at a very moderate expense could prepare an exhibition worth a day's journey to see. Only to think of an aquarium which should include the water-loving plants of the Genesee country alone. The white and fragrant pond lily in the centre—the blue flowered *Pontederia* with its fine foliage near the shore—the silvery spikes of the *Menyanthes* on the margin—the tall and elegant *Cypripedium* on the wet soil, shading the water-cups of the *Sarracenia*—and admitting along side the more brilliant *Calopogon*—the fringed *Orchis*—the fragrant *Pogonia*—and the fine purple of the leafless *A. elusa*. Not far from these, the hooded *Utricularias* with their golden blossoms might intermix with the rosy spikes of the amphibious *Polygonum*—and later—in autumn—the striped flowers of the delicate *Parnassia* with the dewy purple of the *Gerardia*. A few bunches of the wild rice (two kinds) would make a noble display. Even in the edge of winter, the red fruit of the cranberry, projecting from the spongy moss, would be brightly reflected from the water; and the *Prinos*, though leafless at that dreary season, would glitter in the most brilliant scarlet.

Twice as many more might be named, and congregated with representatives from other parts of the temperate zone. The rosy flowers of the Chinese sacred bean (*Cyanus*) would be glorious among the yellow of our native species; and the superb lily, only rising in full vigor from a wet and fertile soil, might be seen eight or ten feet in height, crowned with fifty blossoms.

"The reason why hens do not lay eggs in the winter is because the earth is covered with snow that they can find no gravel, or other calcareous matter to form the shells. If the bones of meat or poultry, be pounded, and given to them, either mixed with their food, or by itself, they will eat it greedily, and will lay eggs as well as in warm weather. When hens are fed with oats, they lay better than when fed on any other grain."

(From the New York Farmer.)

FIBROUS PLANTS.

Consulate C. S. A. Campeche, Jan. 14, 1833.

Dear Sir,—I trust that my various communications from Sisal and this port have reached you, although they were forwarded by indirect conveyance. Yesterday the first vessel direct from the United States, (the merchant schooner *Josefa*,) was announced, and this morning I received the newspapers which contained an account of the horrible events in South Carolina—horrible to an American resident of this theatre of civil war, when anticipating the possibility of similar anarchy in his own blessed country. Let every citizen of the United States who is discontented on account of the errors or abuse of his own state or national government—let him but pass one month in any of the misalled republics of Spanish America, and he will return with an increased admiration of our happy institutions. Cannot South Carolina borrow from Mexico any fruit but its bloody anarchy? She has transplanted from the Old Continent the rice and the cotton which gave prosperity and peace to her inhabitants; and she can introduce from this adjoining section of the New World the Cassave and Squisil, or the bread and cloth materials of analogous climates, which will restore their wealth and tranquillity.

By my statement of the experiment made on the sandy shore of Sisal with the cultivated Sacqui, you have seen that the Agave Sisalana is adapted to the most sterile soils and most exposed situations, and yields a much greater reward to the cultivator than any object of agriculture now existing in the United States. I am happy to state further, that on the almost naked rocks in the vicinity of this city, the cultivated Yasqui, which I caused to be planted about three years since, is now furnishing a second crop of its smooth edged leaves, from which is extracted the "greenish henequen."

I have the still greater satisfaction to add, that the young plants, of which hundreds are born in the centre stalk of the parent, 25 to 30 feet high, which I had placed in a bed during the spring of 1830, are now transplanted into a lot where they appear to rival in vigor the shoots which proceed directly from the roots of the Agave, which were the only ones heretofore used by the natives to form other fields.

The interest which I have manifested regarding these fibrous plants has caused the formation of a company to promote their cultivation—a new epoch in the history of Yucatan, which nothing but jealousy could have effected, and at which I rejoice, notwithstanding the motive which has stimulated these people to this extraordinary exertion. From their "project" I extract what follows: 1st, That in the third year from the time of planting the shoots, each Agave will yield in two cuttings annually at least four pounds of Sisal hemp; 2d, That every two years ten shoots or young Agaves may, or must be, extracted from the space around each mature plant; 3d, That in the third year and every year afterwards, 36,000 plants will yield 1,440 quintals, which at \$6 the quintal equals \$8,640.

Yours, respectfully, H. PERRINE.

(From the New England Farmer.)

PATENT DOMESTIC SILK SPINNER AND TWISTER.

Scituate, 3d Month, 7, 1833.

With confidence I introduce this machine to the public which I have learned from experience to be the best of any yet in use; as I have tried various ways for reeling and spinning silk, but found nothing but what required too much labor and loss to be profitable until I made this machine. This can be used to draw the thread and twist at the same time, cocoons enough to make the thread of any size required, and make it as much or as little as is wanted for weaving, knitting and double and twist the sewing silk in the neatest

manner; all with one operation by twisting it wet from the cocoon into a finished thread, smoother, stronger, and more even, uniting it in its natural gum, better than it can be after it is dried. Silk can be spun on this machine from the cocoons into a thread with less expense or labor than linen, cotton or woolen yarn, and its steady drawing does not break the fibres, as was experienced on other reels.

There is another advantage in using this machine. There is often a loss and perplexity from the silk's tangling, breaking and separating before it is twisted, but with this we may have it all saved and good with a little care in managing the cocoons.

I have had a piece of silk handkerchief spun, and woven in a common loom—reed and harness which obtained a premium at Bridgewater agricultural exhibition. It wove as strong as any other cloth.

Any person, who purchases a machine may learn to spin in two days, and shall have such instructions as are necessary to do it in the best manner gratis by coming to my house, or they may with a few days' trial, by following the directions, learn themselves.

Printed directions shall be furnished to the purchasers of each machine, describing the exact process from the cocoons to warp and filling for cloth or finishing sewing silk. I have had completed on this machine from the cocoons fifteen skeins of well wrought sewing silk in ninety minutes.

ADAM BROOKS.

For farther information relative to this machine, inquire at the Agricultural Warehouse, No. 52 North Market street, Boston.

RURAL ECONOMY.

(From the Genesee Farmer.)

ON THE DIFFERENT BREEDS OF CATTLE.

In the second volume of the Genesee Farmer, a letter is published from the Hon. J. H. Powell on improved cattle, in which he takes much pains to lessen the value of the *Devons*, and exalts the *Short-horn Durhams*. From the known character of the writer, I cannot suppose him capable of being influenced by prejudice or interest, although he was not the owner of *Devons*, but an extensive rearer and vender of the *Durhams*. Yet I am inclined to believe he was not very well acquainted with many valuable properties of the former, and did not realize the great inconveniences attending the latter. In England, where they have abundance of succulent food for winter, and their luxuriant pastures are seldom parched by drought in summer, the *Durhams* answer very well, as the extravagant price of beef in that country will compensate for almost any amount of labor; but, even then, the poorest pastures and the coarsest forage are fed by the smaller cattle. But here, the inconvenience arising from the summer's drought, which so often destroys our pastures; the scarcity of succulent food in winter; the unfitness of the oxen for labor; the great difficulty which the cows experience in calving—together with the low price of our beef, which will not compensate us for extraordinary care,—will, I think, be found reasons sufficient for excluding the *Durhams* from general use.

Now the *Devons* are admirably adapted to the circumstances and wants of western New York. They are fine boned, fat, quick, prove well, are very hardy, and keep easily. The oxen are active, vigorous and docile, well calculated for labor, not being surpassed by any, (not even the New England oxen,) although Mr. Powell thinks them unfit for any thing but light work. They will weigh when fatted from ten to fifteen hundred weight, and the cows from six to eight hundred weight, and from a given quantity of food, they will yield as much beef as the *Durhams*. The cows have no difficulty in calving, are excellent for dairy, giving very rich milk, which

yields a great quantity of butter and cheese, and are not surpassed by the *Durhams* in proportion to the food they consume. The bulls are fine boned, slim horns, clean limbs, and exhibit what is called in horses much blood. They are generally less than the oxen, and when compared with the *Durham* bulls, appear small; but the value of a sire depends upon the goodness of his stock. The color of the full blooded *Devons* is invariably a dark red or bright mahogany, without any white, excepting the brush of the tail, (which does not take that color until they are about a year old, but never fails of being all white at two years old,) or sometimes a little white on the belly.

The celebrated Mr. Coke, of Norfolk, England, had as good an opportunity of being acquainted with the *Devons* as Mr. Powell, and he pronounced them second to none in England, and such is the opinion of the best judges there; if so, they must be much preferable for this country. The following extract is from a valuable little work, entitled "The Experienced Butcher," (and has been republished in the first volume of this State's Agricultural Memoirs, page 284.) "By all judges of cattle, the *Devonshire* breed is confessed to be one of the most beautiful, and at the same time, one of the most valuable which our island (England) produces. They are of large size, and of a red color; the color of the cow varies from a light red to a dark mahogany. They are thin skinned, and silky in the handle. The general height of the bulls is from twelve to fourteen hands, the cows from eleven to twelve, and the oxen from fourteen to fifteen hands high. The *Devon* cattle arrive at maturity sooner than most other breeds. The full grown animals are so valuable that few of the calves are killed. For usefulness in agricultural labor, the oxen are held in the highest estimation; they are well fitted for draught both as to hardness and activity. Worked oxen of this breed attain a larger size than those which are not worked. In excellency of beef, the *Devon* oxen can scarcely be exceeded; and it is a remarkable circumstance, that they will bear driving to London sometimes without the smallest waste, from a distance of more than a hundred miles. The skin is reckoned among the thinner classes, but it improves much in tanning." The celebrated cattle of *Devonshire* are thus described in the *Annals of Agriculture*, No. 172, by Lord Somerville, a native and resident of the county in which these cattle are bred. His lordship first observes, that "to describe the breed not as they might be in imaginary individuals, but as they really are to be found, it may in general be observed, speaking of this as of all other breeds, that conclusions must not be drawn from the size and shape of the bulls, but from the general quality of their stock, certain it is that, individually, handsomer bulls are often to be found in other breeds; and it is certain, that this race, of which the whole produce is brought to view, stands the confessed favorite, or among the very first at Smithfield, where prejudice cannot find the way; and in forming an estimate of merit or demerit, the annual produce is to be the object attended to. This, in oxen, which for superiority of grain, activity in labor, are beyond all competition; and what in horses is termed blood, will be found a right criterion to judge of the bulls which got them." I might add many more proofs of the high estimation in which the *Devons* are held by good judges, but I fear this is already too long.

Yours,

F.

IMPROVEMENT IN CANDLES.—I steep the common wick in lime water, in which I have dissolved a considerable quantity of nitre or saltpetre. By this means I secure a purer flame and a superior light; a more perfect combustion is insured; snuffing is rendered nearly as superfluous as in wax candles, and the candles thus treated do not "run." The wicks must be thoroughly dry before the tallow is put to them.—*Farmer's Reporter*.

(From the Northampton Courier.)

SAGACITY OF BEES.

The instinctive sagacity of the honey bee every farmer has had occasion to notice. A curious instance of contrivance of means and success of ultimate ends, between two swarms was seen in this town last fall. A farmer, while crossing an open lot near the centre of the town, noticed a continued line of bees passing through the air, from one farm house to another. He followed the advancing line and came to its termination, where he found a hive which had been assailed by two foreign swarms, the one he had followed and another diverging off in nearly an opposite direction. By some instinctive understanding between the two swarms, they had united their strength and simultaneously attacked the hive; the struggle was then over and the dead and dying bees belonging to it lay scattered around the hive. The honey had been taken out by the conquerors, who were then carrying it to their own hives, something like fifty pounds having been removed in less than twenty-four hours. It was plain to discover, upon inspection, that a coalition had been formed between the two swarms, to attack and destroy the other, and afterwards to appropriate the honey to their own use. All this was done, but how the understanding was effected or the stipulations drawn up, we leave for the naturalists and curious to decipher.

(From the Genesee Farmer.)

BEE MOTH.

Mr. Editor—There have been several writers in the Farmer, who appear to have had considerable experience in raising bees. I would therefore make the following suggestions, hoping to elicit from some of them information respecting the natural history of the bee moth.

This destructive insect, when it has attained maturity, winds itself up in its web, and passes into the chrysalis state in the corners and upper part of the hive, or among the broken fragments of the comb. The miller must therefore be hatched in the hive, and the question arises, whether it does not immediately deposit its eggs, and prepare for a new progeny before it leaves the hive.

The miller of the silk worm, it is said, deposits its eggs in a few hours after it passes into its winged form, and such is believed to be the fact respecting most of the butterfly kind.

Now if this be a fact respecting the bee miller, I would ask, what can be done to save a hive once infested with the worm, except to destroy the hive, and to substitute another in its place? This I once knew practiced with success. The owner took the infested hive from the stand, substituted another in its place; then with his axe split open the hive containing the bees—took a few pieces of pure comb, and put them into the new hive, to which the bees resorted, took up their abode, and worked well. This was done early in the spring.

A.

(From the Kennebec Farmer.)

FATTENING BEEF.

Monmouth, Feb. 15, 1833.

Mr. Holmes:—I wish to communicate a few observations through the columns of your useful paper, in regard to fattening beef. Much of the beef made in this vicinity, is from cows which, through age, have become unfit for the dairy, and from oxen which are worn out with hard labor. It is customary to milk the cows until August or September, and as soon as they can be dried of their milk, begin to feed them, first with green corn stalks, small corn, potatoes and meal; and the value of the feed given them is generally much more than the value of the beef when slaughtered. The oxen intended for beef are generally worked in the spring as long as they are able to

drag the plough, because it is the last spring's work which they will do, for the owner intends to fatten them.

Now all this appears to me wrong. If those who have old cows which they intend to fatten, would dry them of their milk before they go to the pasture in the spring, and let them have a good pasture and plenty of salt, they will find that they will have much better beef than that which is made from vegetables in the fall, and much cheaper; and a cow thus fattened will have double the quantity of tallow, of those which are milked through the summer. The old and worn out oxen intended for beef, should be well kept through the winter and spring, and corn or meal freely given them, so that they may be in good case when they go to the pasture; one bushel of corn or meal given them in the spring is worth two in the fall. Let them have a good pasture and bleed them once a month or oftener, take but a small quantity of blood at a time. In this way the farmer will find he is amply compensated for the loss of milk from his old cow and for the labor of his worn out oxen.

A FARMER.

MISCELLANEOUS.

(From the New York Commercial Advertiser.)

SAP OF BIRCH TREES—A NEW DRINK.

[Justice to the author of the following communication, requires us to say that it was written off hand, immediately after the appearance of the article in the American, to which it is a reply.]

I saw last evening in the American the following:—
A NEW DRINK.—A correspondent sends us the following extract of a letter.

“By the way, do the people ‘down east’ know that an excellent drink can be made of the sap of birch trees? You may, if you please, communicate it to some newspaper. It is made like wine.”

The next best thing to telling that sap of birch trees makes an excellent drink, is to let us know the process of making it—though, to be sure, they are ‘cute enough ‘down east’ to find any thing out.

Not being acquainted with the editor of that paper, I have sent an answer to the inquiries then made, to you.

The very mention of the beverage is reviving. The birch tree from which the sap is taken for this purpose is the black birch, but yellow or white birch will answer the purpose. The birch of either species abounds more in sap than any other tree of the American forests. An hundred gallons of sap may be taken from a good sized tree in twenty-four hours.* Sixteen gallons of this sap contain about a pound of sugar. It contains a large quantity of fixed air, and is a delightful drink as it runs pure from the tree, and it may be used as freely as the Saratoga waters with safety. The drink is highly exhilarating. Beer may be made in various ways from this sap, but the best I ever drank was made in the following manner:

The trees were tapped in March, as the snow was wasting away, and tubs placed under them to catch the liquor. The crochets were fixed, the lug-pole extended, and the large kettle swung—the sap was put into them, and the fire kindled, and the sap was boiled down to about one-half of the natural quantity—

* “A man much employed in making maple sugar found that for twenty days together, one of the maple trees which he tended, discharged seven gallons and an half each day. A large birch which was tapped in the spring ran at the rate of five gallons an hour when first tapped; and during the season of the running of the sap, it discharged sixty barrels in one spring. The consequence of this waste of the juice was the death of the tree, the ensuing summer.”—*Vide The Natural and Civil History of Vermont by Samuel Williams, L. L. D. and printed at Walpole, by Isaiah Thomas & Co.—1794, p. 75.*

an half pint of the essence of the spruce, an handful of chickenberry leaves, with a small quantity of sassafras or sasaparilla is allotted to a barrel; and if you wish it to be super-excellent, put in as you turn it into the cask, about two quarts of maple syrup to thirty gallons. A few days after the casks are put into the cellar, give them a slight vent while it is in a gentle ferment. The casks should be in a cool place, that the fermentation should be slowly carried on; when this is over, bung it up tight, and in May it will be in the highest perfection.

No drink ever used is more delightful to the taste, or more healthy. It purifies the blood—sits well upon the stomach—and has no intoxicating effect. Had Bacchus known how to make birch beer, he would have thrown down his wine cup and adhered to the beer barrel. The writer of these rules for brewing the eastern birch beer, has tasted of the vintages of many nations;—has drunk from the leathern bottle of Shiraz, “the flagon of Rhenish,” the black glass containing Mountain Malaga,—the clear, inspiring looking taper necked bottles of Champagne; but would forego them all for the pure, well made, well kept cask of birch beer. It is remarkable for clearing the head—and for warming the heart. The New Hampshire troops had been swigging at it when they heard of the Lexington fight, and had a few barrels left when they went on to Bunker Hill—they drank but little else during the whole revolutionary conflict—and what people ever were braver?

Stark drank his tankard of beer until he was turned of ninety, and old Samuel Welsh, of Bow, refreshed the writer with a mug of fine birch beer in a warm day,—drinking freely of it himself, then in his hundred and twelfth year. Is it not conducive to long life? It must be confessed that some of the rising generation in that region, although they loved it dearly, thought it was not so fashionable as brandy; and did not think of offering it to a visitor; but it is to be hoped that this modesty has become quite extinct—and that in some future day the excellence of the birch will be sung with the virtues of the vine; and that the genius of Temperance will adopt the birch tree as an emblem of his complete triumph over all the fiery spirits of the distillery. A YANKEE.

(From the Genesee Farmer.)

SPURRED RYE.

You caution your readers against the use of this article. It is generally believed, I may say *known*, to be poisonous. I well recollect that in the seasons of 1815 and 16, most of the rye crops in New-England were much infested with it, and during these years much mortal sickness prevailed. In many instances the spurred rye was alleged as the cause. My father at that time owned a country grist mill, and had for many years a stout six footer of an overgrown miller to tend it. In the various grists which were brought to the mill for grinding was considerable of this spurred rye, which was easily known by its large black and distorted kernels. The question as to its poisonous qualities was often discussed by the farmers who came to the mill, and the miller who, as was usual with him on any subject where the least matter of science was connected, took the negative side of the question; and by way of proof positive, always made a point of picking out a handful of the ergot from the grist before him, as he sat tending the hopper, and eating it in presence of his combatant.

This I have seen him do oftentimes, say a large table spoonful at a time. He was never injured in the least by it, and is living yet as hale a man as any in the country. I do not mention this fact to confute the opinion that the ergot is poison, for I suppose it to have been reduced to such positive scientific examination as to settle this point, but to note a prominent exception to its general supposed application.

WHITE MULBERRY SEED, &c.

Just received at the American Farmer Office and Seed Store a supply of fresh and genuine WHITE MULBERRY SEED. Also MAMMOUTH PUMPKIN SEED. EARLIEST FRENCH CABBAGE do. EARLY FRENCH, or PARIS WHITE ONION do. ACORN SQUASH do.

Together with a complete assortment of Fresh Garden Seeds, including those raised by the United Society of Shakers at New Lebanon, N. Y.

L. I. HITCHCOCK.

BUFFALO BERRY TREE OR SHEPHERDIA OF THE ROCKY MOUNTAINS.

Just received, a fresh supply of these truly splendid trees, which, when in bearing, are literally loaded with delicious red berries, resembling the Antwerp Currant, and set as thickly on every twig as kernels of corn on the ear. Price \$1 each.

Address, L. I. HITCHCOCK.

FINE MALTESE JACK FOR SALE.

The Subscriber has for sale (on commission) a fine Jack of the breed of the Knight of Malta and Royal Gift. He is six years old, a very powerful animal, a sure foal getter, very gentle and easily managed. Price \$200, delivered in Baltimore. The following are the dimensions of the animal furnished by the owner:

- 4 feet 2 inches in height, (12½ hands)
- 5 " 10 " round the body.
- 3 " 6 " round the neck.
- 1 " 4 " round above the knee.
- 1 " 0 " round the knee.

Apply to L. I. HITCHCOCK, American Farmer Office and Seed Store.

ORCHARD AND HERDS GRASS SEED

For sale at the American Farmer Office and Seed Store, by L. I. HITCHCOCK. Clean Orchard Grass Seed \$3 per bushel. A lot of this seed imperfectly cleared will be sold at \$2.50 per bushel. Herds, \$1 per bushel.

SILKWORM EGGS

For sale at the American Farmer Office and Seed Store, at \$1 per thousand. They can be sent safely by mail if ordered immediately, before the weather becomes warm.

L. I. HITCHCOCK.

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at \$1 per bushel.

L. I. HITCHCOCK, American Farmer Office and Seed Store.

200,000 WHITE MULBERRY TREES.

The Subscriber has on hand and for sale 200,000 White Mulberry Trees of two and three years' growth, which have been transplanted, are in a healthy and thrifty condition, and which he offers for sale at \$1.50 and \$2.00 per hundred, delivered at the nursery.

Also, a few of the Morus Multicaulis, or Chinese White Mulberry.

ASA BUTLER, Suffield, Connecticut.

P. S. All orders (post paid) will be punctually attended to. April 12, —61.

PUBLIC SALE OF DURHAM SHORTHORN-ED CATTLE AND HIGHLY IMPROVED SHEEP

Will be sold on Wednesday, 29th day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd. The highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEDGERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young Lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand.

DAVID MEADE, Administrator.

April 5, —81

IMPROVED DURHAM SHORTHORNS.

Several young BULLS got by Bolivar out of selected cows, — one nearly two years old, two yearlings, and two spring calves, — for sale at the Epsom Farm, seven miles and a half from Baltimore, on the York Turnpike road.

The bull Bolivar was bred by J. Whitaker, from the best stock in England, and imported by J. H. Powel, Esq.

April 12, —11*

FIELD AND GARDEN SEEDS, &c.

J. S. EASTMAN offers the following Seeds for sale, viz. CLOVER, TIMOTHY, MEADOW OAT GRASS, MILET, LUCERNE, COW PEAS, LARGE YELLOW PUMPKIN, and EARLY WHITE CORN.

Also a general assortment of GARDEN SEEDS, and WHITE ONION SETS.

Likewise in store, a general assortment of AGRICULTURAL IMPLEMENTS, embracing almost every article in the farming line, which he will sell low for cash or approved city acceptances.

He must decline opening any new accounts, except with those who will be liberal customers, and can give good references; and all such accounts he expects to be promptly settled once a year; and those who have accounts standing on his books over one year, are desired to settle the same. All Grass Seeds must be considered cash. Liberal discounts will be made on all implements purchased by merchants and others to sell again.

Feb. 15.

SINCLAIR AND MOORES NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices; — after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Bushes, (among which is the much admired Greville,) double Allieas, Honeysuckles, Corcorus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Alantus, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets.

Feb. 22.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—There has been very little variation in the market since our last. Flour remains strictly at former rates, the wagon price of Howard street continuing at \$5.37½, though a few purchases have been made at a trifle below that rate. A very fine cargo of white wheat was sold a few days since at \$1.25; and sales of other kinds of wheat, and other grain have been made within the range of our quotations.

TOBACCO.—Seconds, as in quality, 3 00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 321 hhd. Md.; 54 hhd. Ohio and 16 hhd. Vir.—total 391 hhd.

Flour.—best white wheat family, \$6.75 a 7.25; super Howard-street, 5.11 a 5.50; city mills, 5.37½ a 5.44; city mills extra 5.50 a —.—Corn Meal bbl. 3.25; —Grass, bested wheat, 1.12 a 1.18; white do. — a 1.25; —Corn, white, 69 a 70; yellow, 70 a 71; —Rye, 68 a 70 —OATS, 40 a 43 —BEANS, 75 a 80 —PEAS, 65 a 70 —CLOVER-SEED 8.00 a —TIMOTHY, — a —ORCHARD GRASS 3.00 a —Tall Meadow Oat Grass 2.00 a 2.50.—Herd's, — a —Lucerne — a 37½ lb.—BARLEY,—Flaxseed 1.50 a 1.62—Cotton, Va. 10 a 12—Low, 12 a 13—Alab. 12 a 13—Tenn. 10 a 12; N. THE FARMER.

BALTIMORE, FRIDAY, APRIL 19, 1833.

AMERICAN WINE.—We have received several specimens of wine, lately made by our enterprising countrymen, with requests that we would give our opinion of their qualities. They were all very pleasant to the palate, but obnoxious to the common objection of being sugared and brandied. We cannot recommend such liquors as wine, however delicious they may be as *cordials*. If those who make wine would put the sugar into the must, there would be no need of brandy, and then the wine *would* be wine.

We understand that the culture of the vine is extending in the vicinity of Richmond, and that the Catawba is the favorite variety. Mr. John Carter has a vineyard of considerable extent, and has made two hundred gallons of good wine, which he sold for two dollars per gallon. It was made from the Catawba grape. Mr. Wm. Anderson, of the same place, also has a vineyard of six or eight acres, which he is extending to double that size.

A WORTHY EXAMPLE, for all southern agriculturists, may be found in what follows from a young planter, who is at the same time a good sailor, and a polished scholar and gentleman.

Extract to Mr. Skinner, late editor of the American Farmer:

"Excuse me, when I entreat your kind offices in executing small commissions occasionally. The style of husbandry in this quarter is most wretched, and were not this one of the finest countries in the world, nobody could prosper under it. Old fashioned, inefficient tools are used. I have been assiduous in introducing on my plantations, the most approved implements, from all parts of the union, for my own benefit and as an example to my neighbors; but those things are seldom faithfully made, unless ordered by some friend on the spot. Baltimore, I am inclined to fix upon as my point of supply. I have become passionately fond of agriculture and shall devote myself to it exclusively: fortunately, it is in my power to pursue it as a means of pleasure, as well as of profit. Very soon, I discovered here, universal ignorance of the value of proper arrangement and almost entire neglect to keep up the fertility of the soil. For two years, I permitted the old mode to be followed, while I was collecting materials from observation, reading and experience for the foundation of a system. Last year, I struck into the new plan, and in the course of it, laid off myself, six hundred acres in the horizontal mode, on this place alone. I shall continue every year to mark in that manner, until the whole of my cleared land shall be worked, so as to obviate the washing of the soil. Where full crops of cotton are made, the picking of it out occupies nearly all that portion of the year, which might be otherwise employed in manuring and in making permanent improvements; it is plain, therefore, that on a cotton plantation every operation should refer to a single object. That there may be undivided attention; to a separate portion of this tract, I assign the raising of stock and provision exclusively; and at the mill place, where it extends to Savannah river, I intend to reside, when the buildings are completed, and establish an experimental farm. On this side, no other plough crop, than cotton shall be put in. None of the settlements are more than three and a half or four miles apart, so that I can easily visit them all every day. My manner of running fences and roads is, I believe, altogether new. I am a bold schemer in every thing, but I have advantage over most innovators in being the first to discover when I am wrong, and do not hesitate from false shame to alter my course, in being always eager to profit by the opinions of others, and in not aiming at eccentricity. Without greediness of disposition, involvement or inebriance, I may venture

to lanch out for discovery. It is certain, that unless a speedy change take place in its husbandry, this country must be utterly ruined, and I am not sensible of any feeling so strong, as the wish to contribute, unostentatiously, and however remotely, in effecting a beneficial change. All this, I write by way of apology for aspiring to your aid, without having any personal claim on your attention."

(From the New England Farmer.)

COCKROACHES.

Now is the proper season to clear houses of cockroaches, else, they will soon swarm, and then it will seem almost futile to attempt to do it effectually.

Take a deep plate or dish, and nearly fill the bottom part of it with molasses and water; set it near their haunts, with some chips from the shelf to the edge of the plate or dish, for a *rail-way free bridge*, for these nimble footed beauties to travel on to this sweet bath, and the next morning, a very goodly number of the *last generation* will be found up to their backs indolently revelling in this charming liquid—now, they are not dead but sleepeth, and if thrown out of doors, I will bet my "Cremona to a jewsharp" that the chance is equal for their reviving again and appearing in all their hideous deformity, "hobgoblin and all"—but another death will stop their swift race—viz. the fire; whatever number may be caught, scoop them out of the plate, and lodge them safely in the fire, and you make *good* their retreat, and nothing short of that will do it.

EXPERIENCE.

[We can give a better receipt for getting rid of cockroaches than the above; better, because cheaper and easier, as it costs but two cents and five minutes time. Catch three cockroaches—take care not to hurt them—wrap them in a piece of paper together with *two cents*, carry the package to the market, and slyly put them into a market cart, or wagon, or basket, or any thing else in which country produce is brought to town to sell. In the course of a few hours all the cockroaches will leave the house. This is called *selling* them, by those who practise it; but it would seem more like *buying* them away. If any one doubts the correctness or efficiency of the above receipt, we can give him the name of a very respectable gentleman and lady of this city who practised it themselves. The old gentleman assured us, that on going home to dinner one day, he met at the gate myriads of cockroaches marching out like an army; he mentioned the circumstance to his wife, who informed him that she had *sold* them in the manner above described. We have heard the story from both the gentleman and lady separately, and they most thoroughly believe that the cockroaches left the premises in consequence of the *sale* described. There were none on the premises for a long time afterwards. The respectability of the gentleman and lady, and the positive and serious manner in which they relate the story, absolutely preclude all expression of doubt on the subject, however much we may feel puzzled to account for the fact on principles of "why and because."—*Ed. Am. Farmer.*]

HORTICULTURAL SOCIETY.

A special meeting of this association was held on Saturday, the 13th inst. Amongst the plants exhibited by various members, we noticed the following:

A splendid bouquet of hyacinths, comprising eighteen sorts, all beautiful; some very rare and curious. We remarked several yellow ones, and one of a salmon color tipped with green—Presented by B. I. Cohen, Esq. Vice President of the society, who sent also a fine *Azalea Indica* (the scarlet) in full bloom, and a very tall specimen of *Albica Altissima* with a flower stem of several feet in height. A leaf from the same plant, the proprietor informed us, once measured seven feet in length.

A beautiful species of *Ornithogalum*, supposed *Arabicum*, a very handsome bulbous rooted plant;

flower stem about two feet high, bearing at the summit a corymb of about a dozen blossoms, pure white, with the exception of a small green spot at the tip of each division. Each flower is about an inch and a half in diameter, cup shaped; the *corolla* is very dark, presenting the appearance of a black spot, in the centre of the white flower, and rendering very conspicuous the six stamens which are arranged regularly around it.—Presented by Mr. Kurtz, who also exhibited flowers of *Cydonia Japonica*, and of *Fritillaria Meleagris*, or chess board Fritillary. The flower of this is bell-shaped, color without a greenish red, the inner surface marked with red and white squares in the same manner as a chess board. Also a new *Azalea*, imported from Canton some years ago, with lilac colored flowers.

A large and beautiful specimen of *Jacacia Armata*, five feet high, and covered with a profusion of flowers. *Ulicium floridanum*, in flower; a fine plant. *Valtheimia viridifolia*, a handsome plant, with a flower stem a foot high, bearing a large and compact cluster of long, tubular, pendulous flowers, of a flesh color, fading to white at the extremities; leaves large and luxuriant, of rich green, whence the specific name. Two varieties of *Primula auricula*, crimson and purple. Ninety one varieties of *Primula polyanthus*, really a pretty collection of every combination of color; all raised from seeds, and flowering for the first time this season. *Reseda alba*, a species which produces more beautiful flowers, but does not possess the delicious odor for which its well known congener, *Reseda odorata*, or nignonne, is so deservedly esteemed. The above were presented by Mr. Jno. Feast.

Specimens of *Tritonia crocata*, (formerly *Ixia*), and two new varieties obtained from seeds of the same by Zebulon Waters, Esq.—But undoubtedly the finest plant exhibited on this occasion was a *Cereus flagelliformis*, from the green house of the same gentleman. It was a well grown specimen, having at least fifty branches or stems in which several members counted fifty flowers or flower buds. The flowers are from two to three inches in length, of a most delicate rose color of different degrees of depth and richness, sometimes intermingled with a delicate tint of purple. They form a striking contrast with the scourge-shaped stems bristled with small spines, which same spines, though they present a very repulsive appearance at first, on a closer acquaintance prove to be very "insinuating." It is impossible to give any description that will convey a correct idea of this beautiful and singular production.

We must not forget to mention the *Hortensia rosea*, a handsome variety; *Ranunculus ficaria*, double; *Statice armeria*, or thrift, (a very desirable thing, by the way,) and a specimen of *Calampelos* or *Eccremocarpus caber*, a handsome twining green house shrub; all presented by Mr. J. Feast.

The room in which the society meets, in the Athenaeum, is large enough to accommodate a good many more members than we have yet seen at any meeting of the society. Why do not our fellow citizens come forward, and hand in their names to be enrolled in the list of members of an association, which requires but a general co-operation to be of immense public benefit? We hope the citizens of Baltimore will not suffer the efforts of the association to be paralyzed for want of that co-operation on their part.

D***.

RADISHES.—Most of our garden grounds are too rich for the radish; and but few gardens are found that do not contain more or less of the *wire worm*.—Hence we are induced to make experiments until we have raised them at least semi-transparent and as brittle as glass. Our method is, merely to mix two parts of sand with one part of common garden earth, and add a small quantity of stable manure. Or earth of a clayey nature is preferable to the garden earth. Since adopting the above method we have not failed in a single instance of raising an abundance of smooth, clear, and fine flavored radishes.—*Hing. Gazette.*

AGRICULTURE.

(From Proceedings of the N. Y. State Agricul. Society.)

ON THE CULTURE OF INDIAN CORN.

COMMUNICATION FROM JESSE BUEL.

There is no crop more beneficial to the American farmer than Indian corn. An eminent agriculturist, the late John Taylor of Virginia, called it the "meal, meadow, and manure," of the farm. It is convertible into human food in more forms than any other grain; its value in fattening domestic animals is not exceeded by any product of the farm; and no crop returns more to the soil than this does in the form of manure. There are two important requisites, however, to its profitable cultivation. The first is, that the soil be adapted to its growth; and the second, that the crop be well fed and well tended; for food and attention are as important to the plant as to the animal. Ordinarily speaking, it costs less to take care of a good crop of corn, on proper corn land, than it does of a bad crop on land not adapted to its culture. The first is light and dry. The latter stiff, wet or grassy. I put the average expense of cultivating and securing an acre, at \$15,* including a fair rent, though it ordinarily exceeds this sum. The farmer, therefore, who obtains thirty bushels from the acre, estimating the grain at 50 cents per bushel, gets a fair compensation for his labor, and the use of his land. Whatever the product falls short of this is an absolute loss; and whatever it may exceed it is net gain. Thus the man who gets but twenty bushels from the acre, loses upon this estimate, \$20 worth of his labor, on four acres. He who raises 80 bushels an acre, on the other hand, realizes a net profit of \$100 from four acres—making a difference in the profits of the two farmers, in the management of four acres of corn, of *one hundred and twenty dollars!* These data are sufficiently accurate to show the importance of the two requisites I have suggested, and the value of a little calculation in the business of farming. The habit of noting down the expense, as well as the product of a crop, and thus ascertaining the relative profit and loss, is highly advantageous to the practical farmer, and one which cannot be too strenuously inculcated. It will perhaps be said, that I ought to add the value of the manure which is employed in the large crop; but I reply, that I offset this against the increased forage which this crop furnishes. Besides, by applying the manure in the unfermented state in which it is generally found in the spring, it will be as beneficial to the succeeding crops, as though it had lain and fermented in the yard, and been applied in the usual way in the autumn †

* Estimated expense of cultivating an acre of Indian corn.

One ploughing, (suppose a clover lay,)	\$2 00
Harrowing and planting,	2 00
Two hoeings, 4 days and horse team,	3 75
Harvesting, 2 days,	1 50
Cutting and harvesting stalks,	1 50
Rent,	5 00

—\$15 75

† Stable and yard manures lose 50 per cent. by the fermentation they undergo in the yard during the summer. This loss consists of the gases which are evolved in the process of rotting, and of the fluids which sink into the earth, or are carried off by the rains. Plants receive their food either in a gaseous or liquid form. If manure rots in the soil, neither these gases or fluids are lost: the earth retains, and the roots of the plants imbibe them. Yet recent manures are not proper to be applied to small grains. They cause too rank a growth of straw, and are apt to induce rust and mildew. Thus a crop of corn, potatoes, or ruta baga may be fed and fattened, if I may use the expression, upon the dung which is destined to nourish the wheat crop, without deteriorating its value for the latter purpose, if it is applied to the corn, &c. before it has fermented.

The soils adapted to the culture of Indian corn, are such as are permeable to heat, air, and the roots of the plant, and embrace those denominated sandy, gravelly and loamy. Corn will not succeed well on grounds that are stiff, hard or wet. The roots grow to as great a length as the stalks, and the soil must be permeable to permit their free extension.

The manures used are generally yard and stable dung, and plaster of paris, (sulphate of lime.) The first ought to be abundant; as upon the fertility which it induces, depends the profit of the crop. Long or unfermented manure is to be preferred. It decomposes as the wants of the plant require it; while its mechanical operation, in rendering the soil light and porous, is beneficial to the crop. It should be equally spread over the whole surface, before it is ploughed under. It then continues to afford fresh pasture to the roots till the corn has matured, and is in its place to benefit the succeeding crop. If put into the hills, the roots soon extend beyond its influence, it does not so readily decompose, and the subsequent crop is prejudiced from its partial distribution in the soil. In a rotation of four or five years, in which this crop receives the manure, twenty-five or thirty ordinary loads may be applied to one acre with greater profit, than to two or three acres. Every addition tells in the product; and there is scarcely any danger of manuring too high for this favorite crop. Gypsum is applied broadcast before the last ploughing or harrowing, or strewed on the hills after hoeing. I pursue the first method, at the rate of a bushel to the acre. ‡

The best preparation for a corn crop is a clover or other grass lay, or lea, well covered with a long manure, recently spread, neatly ploughed, and harrowed lengthwise of the furrow. A roller may precede the harrow with advantage. The time of performing these operations depends upon the texture of the soil, and the quality of the sod. If the first is inclining to clay, or the latter tough or of long continuance, the ploughing may be performed the preceding autumn; but where sand or gravel greatly preponderate, or the sod is light and tender, it is best performed in the spring, and as near to the planting as convenient. The harrow at least should immediately precede planting. All seeds do best when put into the fresh stirred mold. Stiff lands are ameliorated and broken down by fall ploughing; but light lands are rather prejudiced by it. When corn is preceded by a filled crop, the ground should be furrowed, and the seed deposited in the bottoms of the furrows. Where there is a sod, the rows should be superficially marked, and the seed planted upon the surface.

* We are on the northern border of the maize zone, and should make up for defect in climate by selecting soils into which the heat readily penetrates. Air, besides conveying warmth in summer, imparts fertility by the vegetable food which is always suspended in it in the form of gases. Dews are also charged with these properties of vegetable nutriment, and when the soil is porous, they settle down as in a sponge, and impart fertility to the roots (the true mouths) of plants.

‡ I adopt the opinion of Davy, as the *modus operandi* of plaster of paris, that it forms a necessary constituent of plants which it benefits, and is of no direct benefit to plants which do not afford it on analysis. Among the first are the clovers, corn, potatoes, and generally such plants as have broad or succulent leaves, while the latter embrace calumiferous grains and grasses, as wheat, rye, timothy, &c. Critical observation for years has confirmed me in this conclusion. Gypsum must be rendered soluble before it can be taken up by the mouths of plants, and it requires 650 parts of water to dissolve one of this mineral. I infer from these facts, that by burying it in the soil, it more readily dissolves, and is more accessible to the mouths of plants, than if spread upon the surface of the ground. I am induced, from these views of the subject, to sow plaster, on grass grounds, in March, and upon corn and potato grounds before the last ploughing for these crops. The latter was recommended and practised by the distinguished agriculturists, the late Mr. Taylor of Virginia, and Judge Peters, of Pennsylvania.

Where the field is flat, or the sub-soil retentive of moisture, the land should be laid in ridges, that the excess of water which falls may pass off in the furrows.

The time of planting must vary in different districts and in different seasons. The ground should be sufficiently warmed by vernal heat to cause a speedy germination. Natural vegetation affords the best guide. My rule has been to plant when the apple is bursting its blossom buds, which has generally been between the 12th and 20th of May.

Preparation of the seed.—The enemies to be combated are the wire worm, brown grub, birds and squirrels. Of these the first and two last prey upon the kernels, and against these tar offers a complete protection. I soak my seed 12 to 20 hours in hot water, in which is dissolved a few ounces of crude saltpetre, and then add (say to 8 quarts of seed) half a pint of tar, previously warmed and diluted with a quart of warm water. The mass is well stirred, the corn taken out and as much plaster added as will adhere to the grain. This impregnates and partially coats the seed with the tar. The experience of years will warrant me in confidently recommending this as a protection for the seed.

The manner of planting is ordinarily in hills, from two and a half to six feet apart, according to the variety of corn, the strength of the soil, and the fancy of the cultivator. The usual distance in my neighborhood is three feet. Some, however plant in drills of one, two and three rows, by which a greater crop is unquestionably obtained, though the expense of culture is somewhat increased.* The quantity of seed should be double, and may be quadruple† what is required to stand. It is well known that a great difference is manifest in the appearance of the plants.

* The following table exhibits the difference in product of various methods of planting, and serves also to explain the manner in which large crops of this grain have been obtained. I have assumed in the estimate, that each stock produces one ear of corn, and that the ears average one gill of shelled grain. This is estimating the product low; for while I am penning this (October) I find that my largest ears give two gills, and 100 fair ears half a bushel of shelled corn. The calculation is also predicated upon the supposition, that there is no deficiency in the number of stocks, a contingency pretty sure on my method of planting.

	Hills.	bush.	qts.
1. An acre in hills, 4 feet apart, each way, will produce	2722	42	16
2. The same, 3 by 3 feet,	4840	73	20
3. The same, 3 by 2½ feet,	5808	93	28
4. The same in drills, at 3 feet, plants 6 in. apart, in the drills,	29,040	113	14
5. The same in do. 2 rows in a drill, 6 in. apart, and the plants 9 in. and 3 feet 9 inches from centre of drills thus,	30,970	120	31
6. The same in do. 3 rows in a drill, as above, 3 ft. from centres of drills,	43,560	170	5

The fifth mode I have tried. The ground was highly manured, the crop twice cleaned, and the entire acre gathered and weighed accurately, the same day. The product in ears was 103 baskets, each 84 lbs. net, and 65 lbs. over. The last basket was shelled and measured, which showed a product on the acre of 118 bushels 10 quarts. I gathered at the rate of more than 100 bushels the acre, from four rods planted in the third method, last summer, the result ascertained in the most accurate manner. Corn shrinks about 20 per cent. after it is cribbed. The sixth mode is the one by which the Messrs. Pratts, of Madison county, obtained the prodigious crop of 150 bushels per acre. These gentlemen, I am told, are of opinion, that the product of an acre may be increased to 200 bushels.

‡ I am told the Messrs. Pratts, above alluded to, used seven bushels of seed to the acre, the plants being subsequently reduced to the requisite number.

Some appear feeble and sickly, which the best nursing will not render productive. The expense of seed, and the labor of pulling up all but three or four of the strongest plants in a hill, it is believed will be amply remunerated by the increased product. If the seed is covered, as it should be, with fine mold only, and not too deep, we may at least calculate upon every hill or drill having its requisite number of plants.

The after culture consists in keeping the soil loose and free from weeds, which is ordinarily accomplished by two dressings, and in thinning the plants, which latter may be done the first hoeing, or partially omitted till the last. The practice of ploughing among corn, and of making large hills, is justly getting into disrepute: for the plough bruises and cuts the roots of the plants, turns up the sod and manure to waste, and renders the crop more liable to suffer by drought. The first dressing should be performed as soon as the size of the plants will permit, and the best implement to precede the hoe is a corn harrow, adapted to the width of the rows, which every farmer can make. This will destroy most of the weeds and pulverise the soil. The second hoeing should be performed before or as soon as the tassels appear, and may be preceded by the corn harrow, a shallow furrow of the plough, or what is better than either, by the cultivator.* A slight earthing is beneficial, providing the earth is scraped from the surface, and the sod and manure not exposed. It will be found beneficial to run the harrow or cultivator a third, and even a fourth time, between the rows, to destroy weeds and loosen the surface, particularly if the season is dry.

In harvesting the crop, one of three modes is adopted, viz. 1. The corn is cut at the surface of the ground, when the grain has become glazed, or hard upon the outside, put immediately into stooks, and when sufficiently dried, the corn and stalks are separated, and both secured. 2. The tops are taken off when the corn has become glazed, and the grain permitted to remain till October or November upon the outs. Or, 3. Both corn and stalks are left standing till the grain has fully ripened, and the latter become dry, when both are secured. There are other modes, such as leaving the butts or entire stalks, in the field, after the grain is gathered; but these are so wasteful and slovenly as not to merit consideration. The stalks, blades, and tops of corn, if well secured are an excellent fodder for neat cattle. If cut, or cut and steamed, so that they can be readily nasticated, they are superior to hay. Besides, their fertilizing properties, as a manure, are greatly augmented by being fed out in the cattle yard, and imbibing the urine and liquids which always there abound, and which are lost to the farm, in ordinary yards, with-

*The cultivator is made in the form of a triangular harrow, with two bulls; or if intended to be graduated to different widths, a centre bull is added, to which the exterior ones are attached by hinges. Iron slats, fixed to the exterior bulls, pass through a mortice in the centre one, perforated with holes, through which an iron pin passes to hold them at the graduated width. The teeth may be in any approved form, or reasonable number. The cultivator I use has five teeth, two in each of the outward, and one upon the centre timber. The teeth have a stout shank, with a duck's foot termination, four inches broad, somewhat cylindrical, rounded at the point, and inclined forward in an angle of 30 or 40°. This implement is useful for other purposes; and may be used, like Beaton's, as a substitute for the plough, in preparing light soils for a crop. The handles are attached to the centre piece. The teeth have a shoulder, on the under side of the timber, and are fastened with screws and nuts above.

† Some entertain a mistaken notion, that it is prejudicial to stir the soil among corn in dry weather, and others that weeds serve to prevent the evaporation of moisture by a hot sun. The reverse of these opinions is true. The exhaustion of moisture by a plant is in the ratio of the surface of its leaves and stocks presented to the sun and air.

out an abundance of dry litter to take them up. By the first of these methods, the crop may be secured before the autumnal rains; the value of the fodder is increased, and the ground is cleared in time for a winter crop of wheat or rye. The second mode impairs the value of the forage, requires more labor, and does not increase the quantity, or improve the quality, of the grain. The third mode requires the same labor as the first, may improve the quality of the grain, but must inevitably deteriorate the quality of the fodder. The corn cannot be husked too promptly after it is gathered from the field. If permitted to heat, the value of the grain is seriously impaired.

Saving seed.—The fairest and soundest ears are either selected in the field, or at the time of husking, a few of the husks being left on, braided and preserved in an airy situation till wanted for use.

In making a choice of sorts, the object should be to obtain the varieties which ripen early, and afford the greatest crop. I think these two properties are best combined in a twelve rowed kind which I obtained from Vermont some years ago, and which I call Dutch corn, from the name of the gentleman from whom I received it. It is earlier than the common eight rowed yellow, or any other field variety I have seen; and at the same time gives the greatest product. I have invariably cut the crop in the first fourteen days of September, and once in the last week in August. The cob is large, but the grain is so compact upon it, that two bushels of sound ears have yielded five pecks of shelled grain, weighing 62 lbs. the bushel.

In securing the fodder, precaution must be used. The butts become wet by standing on the ground, and if placed in large stacks, or in the barn, the moisture which they contain often induces fermentation and moldiness. To avoid this I put them first in stacks so small, that the whole of the butts are exposed upon the outer surface; and when thoroughly dry they may be taken to the barn, or left to be moved as they are wanted to be fed out—merely regarding the propriety of removing a whole stack at the same time.

(From the Western Agriculturist.)

LIVE FENCES.

In England, the plant in most common use for making hedges, is the white thorn. They are propagated by sowing the haws in drills like peas, where they usually remain until they are taken up to be planted in the hedge. The white thorn is not a native of this country, but will grow here as rapidly as it does in England. The haws of this plant may be had at Liverpool or London in the months of November and December, preserved in sand in barrels. The cost is not more than two dollars a barrel, and three barrels would be sufficient to hedge a common sized farm. Many other plants are also used in that country, such as the holly, the larch, the alder, and the beech, which latter is found to answer remarkably well in cold, wet, clayey soils.

Experiments in different parts of the United States within the last thirty years, have established the fact, that we have a variety of plants well adapt-

ed to all the purposes of hedging. Among these may be enumerated several varieties of the American thorn, the cedar, the holly, the crab, the honey locust, the beech, the willow, the hemlock, and the black locust. Among the more valuable of these may be named the cedar, several varieties of thorn, the honey locust, the hemlock, and the crab, all of which may be propagated from the seed.

The mode of raising the "American" thorn, one of the varieties of the common haw thorn, as practised most successfully, by Mr. Thomas Mann, of the District of Columbia, is the following: The seed are to be carefully extricated from the berries, by moderate pounding with a wooden pestle, after which the stones are to be washed perfectly clean from the pumice, by rubbing them with the hand in water. They should then be placed in a deep box, loosely made, and perforated at the bottom with holes, to permit the water to escape. This box should then be covered with oak leaves or moss, and placed out of doors in some secure but bleak cold situation, and protected from mice and ground squirrels. No earth need be mixed with the seed, nor is it material how often the seed are frozen. On the approach of spring, the seed are to be inspected every two or three days, and so soon as they begin to feel slimy, it indicates that the shells of the stones are about to open. As early as the weather will permit, a bed of free, rich, deep, black loam, rather inclined to moisture than dryness, and situate rather at the bottom than the top of a height, is to be prepared. It should be carefully dug to the depth of twelve or fifteen inches. So soon as the small point of the rootlet of some of the seed becomes visible, the seed are to be sown, in beds about four feet wide, separated by alleys fifteen or eighteen inches in width. The seed ought to be rolled in plaster of paris at the time of sowing, and scattered about an inch apart,—half an inch of fine mold is sufficient for the covering. If the weather is favorable, the young plants will appear in a few days. The whole process may be summed up in a few words:—clear the stones well from the pumice of the berries, keep them damp through winter, and at the proper time in the spring, place them in beds well prepared.

For the purpose of raising a nursery of cedar plants, let the berries be gathered in November and December, and having rubbed off, as far as practicable, the resinous substance in which the seeds are enveloped, mix them with unslaked ashes, in which let them remain for two weeks; then plant them in drills after the manner of planting peas, and they will vegetate and come up the following spring. If well nursed, they will be ready for removal into a hedge in about two years. The trenches into which they are to be placed, should be prepared with light rich earth. The first of March is the proper time for planting them. When the plants have attained the height of three feet, the trimming should be commenced, and the best time for this operation is the middle of summer. A hedge of great beauty, strength and durability, may thus be formed in about seven years from the time of planting. It should be borne in mind that the more thoroughly the seeds are cleaned, and the earlier the plants are removed in the spring, the better. Col. John Taylor, of Virginia, the author of *Arator*, who has paid great attention to the cultivation of cedar hedges, says they should be transplanted in the three winter months, and in March. They should be taken up in such a manner, if possible, as not to remove the earth in immediate contact with the roots, and in this condition placed in their proper situation in the hedge. The smaller the cedars are when removed, the better. An annual trimming is indispensably necessary for the thickening of the hedge. The richer the ground, the better. The cedars should be hoed twice a year, until they attain the size at which they are to remain. The same writer adds, "The holly promises every thing as a shrub for live fences, but I have never tried it, nor do

ed to all the purposes of hedging. Among these may be enumerated several varieties of the American thorn, the cedar, the holly, the crab, the honey locust, the beech, the willow, the hemlock, and the black locust. Among the more valuable of these may be named the cedar, several varieties of thorn, the honey locust, the hemlock, and the crab, all of which may be propagated from the seed.

I know whether its seed will vegetate more kindly than those of the cedar. My hedge of cedar is the best I ever saw, and improves yearly."

The honey locust of our forest is easily propagated from the seed. The plants thrive remarkably well, and owing to the powerful thorns with which they are clothed, form, when cultivated into a hedge, an impassable barrier, even in a single row. It is less beautiful than the cedar or the holly, but for outside fences, designed to resist the depredations of the animals that are running at large, it will perhaps, be found that the honey locust hedge has advantage over either of the before mentioned plants. It grows in most abundance, upon, and indeed may be said to be a native of the rich lands. Hence the importance of rendering the ground rich in which a hedge of this plant is about to be placed. J. C. Short, Esq. of this country, has made a successful experiment with the honey locust, and is very favorably impressed with its value for making live fences. Its foliage is beautiful, folding the lobes of the leaves together every evening, like the clover and some other plants.

The common crab which abounds in our woods, is another plant well calculated for hedging. It possesses all the qualities to render it equal to the English thorn. In one particular, it has peculiar claims on the attention of farmers—the beauty and fragrance of its flowers. For these it is unsurpassed by any other tree or shrub to be found in our forest. It may be readily propagated from the seed in the manner that the common apple tree is raised. An English gentleman, now a resident of this country, who is making some valuable experiments in hedging, has a crab hedge, which he thinks equal in all, and superior in some respects to those made of the English thorn. Among other claims to superiority over either the English or American thorn, is that of its rapid growth. From the experiments made by this individual, it appears that the crab hedge will come to perfection in one-third less time than either the indigenous or foreign thorn.

The hemlock, in the opinion of Richard Peters, Esq. of Pennsylvania, is a plant of equal value with that of any other to be found in our country, for the formation of hedges. It retains its foliage through winter better than most of the resinous tribe. It grows more rapidly than the cedar, and can be raised with but little trouble, from the cones. It thrives well in the shade, and when in bloom, is the most beautiful of all its tribe. The limbs grow horizontally and longer than those of cedar. The *layers* will readily take root. The spring is the best season for transplanting them. The plant may be easily trimmed with the shears.

In low wet grounds, the willow makes a thrifty and substantial fence. The white mulberry will also form a good hedge, but bearing no thorns, and the leaves being attractive to cattle they are apt to prey upon it. Its introduction, however, whether for hedges or for ornament, about a farm, is becoming a matter of deep importance, in consequence of the leaves affording the most nutritious and valuable kind of food in the rearing of silkworms.

That hedges are cheaper and more durable than dead fences made of wood, is, we believe, the concurrent opinion of nearly all the writers and experimentalists, both of Great Britain and this country. Cobbett says, that in this country, a hedge with double rows of the English white thorn, nine hundred feet in length, can be made, that will cost, when five years old, including plants, planting, cultivation and clipping, but fifty-three dollars. There are hedges now standing in England that are from one hundred to three hundred years old. From these data, the farmer can make his own calculations between the cost and relative value of worm fences and live hedges for inclosing.

Another writer in the American Farmer, says, that a good hedge of the American thorn, when seven years old, will cost for every sixty perches, twenty-

four dollars and seventy-five cents. For a farm of one hundred acres, divided into ten fields, twenty-five hundred pannels of post and rail fence would be required, which at seventy-five cents a pannel, would amount to \$1875. The hedge fence for this same farm, with similar divisions, at the foregoing estimate, would cost \$1031, leaving a clear balance, in the original cost, of \$844 in favor of the live fence. At the end of one hundred years, the hedge, with a small annual expenditure of labor upon it, will be as good or better than it was at the end of the first seven years. The post and rail fence, in the course of one hundred years, would require at least six renewals. Surely no further illustrations upon this point need be made, to secure the early attention of the farmers of the west, to this important part of their agricultural labors. It is to be borne in mind, moreover, that hedges are not, like dead fences, liable to be blown down by the winds; nor can they, like the latter be readily overthrown by unruly animals. They are better safeguards around orchards, vineyards and gardens, to protect them against the depredations of men, than the common fences, and finally, they are ornamental in the highest degree to a farm, a matter that will not be overlooked by the husbandman of taste and intelligence.

Another consideration in favor of an early resort to live fences, arises from the fact, that in many parts of Kentucky and Ohio, the timber necessary for the construction of dead fences is becoming scarce. Such has been the excessive and wanton destruction of the forest trees in these states, that although it is less than half a century since the silence of the wilderness was first broken by the sound of the axe, it is a lamentable fact, that many farms are already without the timber necessary for another renewal of their fences. This is a growing evil in the land, and no alternative will shortly be left our farmers but the rearing of hedges. Whenever the experiment, with live fences, shall have been fairly made, we predict that the only regret of the agriculturist will be, that he had not sooner entered upon the system, and thus preserved, at least a part of the oaks and poplars and chestnuts that once, in towering magnificence, spread their verdant branches over his lands.

In conclusion, we propose to make a few observations upon the best modes of lessening the evils so loudly complained of by the western agriculturists, arising from their present system of inclosures.

The first and most important step is that of procuring the passage of a law prohibiting, absolutely, the running at large of horses, cattle, sheep, and more especially hogs. This is a measure that can work out no injury to the rich or the poor, but on the contrary will confer signal advantages upon all classes of the community. No time should be lost in circulating petitions, praying the legislature for the passage of such an act, and no candidate who will not pledge himself to advocate the passage of such a law, should hereafter receive the votes of a single husbandman, who is not willing to see his grains and his fruits, which have been nourished by the sweat of his brow, annually eat up or trampled down by hungry and unruly animals. Our legislators should be told, (for it is a lamentable fact that many who are annually elected, have not the intelligence to make the discovery themselves,) that protecting the farms of their constituents from the depredations of lawless hogs and cattle, is a matter of deeper importance, and better suited to their talents, than spending a session at the capital, tinkering constitutions, or electing presidents. The apathy of our farmers on this subject, is truly marvellous. They act and vote for representatives as if they themselves had nothing at stake. Instead of electing, as their legislators, experienced, intelligent and practical men, they suffer themselves, year after year, to be enojed of their votes by political demagogues, who have neither the inclination nor judgment for pursuing the interests of their constituents. We hesitate not in saying that a law of the

kind here proposed, will do more in preserving the peace of neighborhoods, and in lessening the evils growing out of the want of permanent and substantial fences, than any other measure that can be suggested.

In the second place, it is manifest that where stone abounds upon the surface of a farm, in such situations, that it need not be hauled more than three or four hundred yards, sound policy will dictate the construction of stone fences in preference to those of dead timber. The economy of this system of enclosure, however, will greatly depend upon the manner of constructing the wall and the facility of procuring the material. But it is perfectly obvious that stone fences can never be generally adopted throughout the country. In certain situations and under certain circumstances they will be found highly advantageous.

Lastly, it has been made apparent, we think, that live fences or hedges, combine more economy, security and permanency than any other description of inclosures that has yet been adopted. We do not propose to re-enter upon the examination of their superior advantages. Enough, it is believed, has been said to secure for them the early attention of the farmers of the West. From what has been advanced upon the rearing of hedges, it will be perceived that it requires six or seven years to bring one to perfection. This is about the period that a common worm fence will last, provided it have some annual repairs. Young hedges need some kind of protection for the first three or four years from the depredations of animals. The existing fences will answer very well for this purpose. If then those farmers who now have their grounds enclosed with dead timber, were forthwith to plant out beside their fences, hedges of thorn, locust, crab, or cedar, instead of an expensive and laborous renewal of the former at the end of seven years, they would have in their places what in England is emphatically called an "everlasting fence," most pleasantly ornamental to their farms, and presenting an almost impervious barrier both to men and animals. This once attained together with the passage of a law prohibiting the running at large of animals, and the "fretting leprosy" of the land will be eradicated. The main leak being stopped, the farmer's cup of bliss will be full.

HORTICULTURE.

(From the Genesee Farmer.)

EXPERIMENTS ON THE CULTURE OF SQUASHES AND MELONS.

Gratfield, 3 mo. 27, 1853.

About three years ago, having a surplus of stable manure in the garden, I had it formed into a narrow ridge, about two feet high, and then covered over to the depth of three or four inches with common soil, in the same manner as we bury turnips and potatoes. This was intended as a preparatory step towards converting it into compost; but afterwards finding no suitable spot in any other part of the garden for squashes, I concluded to let it remain undisturbed till autumn, and put in the seeds at proper distances, singly, along the top of the ridge. The plants were the most productive that I had seen in many years.

Last spring we carted yellow pit-sand from a depth of two or three feet, into the garden; and after mixing with it a liberal portion of the scrapings of the barnyard, it was made into a sharp ridge about two feet in height, for sweet potatoes. Not having sprouts enough to plant the whole, however, a part remained unoccupied. It so happened that a package of rare seeds, generously sent me by a distant horticulturist, and which had been detained on the way, arrived a month after the usual time for planting; and among these were two rare kinds of squashes. As this ridge was the only ground that I had unappropriated, I planted the latter seeds on its top. The growth was most remarkable, and I have never seen squashes on

the richest alluvial soils that equalled them in luxuriance.

Although in both these cases, the supply of manure was plentiful, yet I ascribe much of my success to the plants growing on a ridge from which the surplus water in rainy weather, could rapidly pass off. In a former paper,* I have spoken of the advantages of planting melons on ridges; and some time in the last summer, I saw an article written by my friend Richard M. Williams, who had anticipated me in this mode of culture. But whoever may have the honor of the first discovery, we who follow in a track so judiciously marked out, may have quite as much profit; and I recommend this method of raising melons and squashes to all who have to cultivate heavy lands. As his remarks have not yet appeared in the Genesee Farmer, I will take the liberty to make some extracts:

"About the year 1802, I had some grounds ridged for sweet potatoes; when about to plant, my foreman asked me for some watermelon seeds; I gave him about a gill, which he distributed among the planting hands, directing them to plant one seed once in about a rod, near the top of the ridge.

"These vines grew and flourished astonishingly, producing from four to six melons each, most of which were three feet long, and from six to nine inches in diameter, of very fine flavor, and sold readily at the Savannah market from 62½ to 75 cents each, so that I received about \$3.75 from each vine.

"The same season, I took unwearied pains to prepare about an acre of ground, which I directed to be planted on a level in the Yankee fashion. My foreman, old Tom, told me, "*him no do, massa, him all spoil*;" in fact I never scraped five dollars profit from the whole acre. The sun and rain spoiled the whole of them. My cow-yard contained about a quarter of an acre; I ridged about half of it, and planted it with watermelons; from this small patch I sold rising of seventy-five dollars worth of melons. The patches were all planted from the same seed, and the soil was clear sand."

It appears then that this method has been long practised by the negroes in Georgia. About fifteen years before the period alluded to, a near neighbor of my father's had the finest water melons that he had ever raised, owing to the following circumstances: A heap of dark gray sand from the river, had been left in the yard—a remnant not used by the masons; and into this, either by design or accident, some of the children had put the seeds. It does not appear, however, that any further advantage was taken of this unexpected and successful discovery. D. T.

(From the New England Farmer)

ASPARAGUS.

It has formerly been thought necessary to make a very laborious and expensive process of the cultivation of asparagus, but it has more recently been ascertained that the old modes of growing that valuable esculent may be dispensed with, and asparagus raised with about as much facility as potatoes. The Hon. John Welles thus describes his method, which we believe might be adopted, generally, to great advantage.

"A piece of ground was taken of a deep rich soil, after a common corn crop was taken off, the land was ploughed and manured in the usual course. Holes were then dug twelve to fourteen inches in depth, and about the same distance apart, and two or three shovels full of compost manure were mixed with a part of the earth. The roots of a year's growth were then inserted at about six inches in depth. This bed has flourished, and has been thought as productive as any whatever. I at the same time, with a view to a more full and fair course of experiments, took a piece of land in another place of opposite character, being of thin light soil, and adopted a like course and

the result has been equally favorable. The only difference to be noted, was that the latter was more early in coming forward from the nature of the soil.

"However rare it may be that there is any over cultivation or preparation of the soil for any vegetable production, it would seem here to be the case. The old forms appear to have been kept up, and to have discouraged a more general diffusion of this valuable plant."

"Dr. Deane, in his husbandry, has somewhat simplified the matter, but not sufficiently. His proposed method of placing the roots at six, eight, and nine inches apart is quite too near. The duration of ten or twelve years is quite a mistaken one: it lasts with us double that period."

Mr. Armstrong, in the second volume of the "*Memoirs of the New York Board of Agriculture*," says, It has been asserted, and with sufficient confidence, that a pickle of salt and water of the ordinary strength for preserving meat may be very usefully applied to asparagus beds in the spring. The effects ascribed to it are its stimulating power over the crop, and its tendency to destroy the seeds of weeds and insects lying near the surface. Experiments on this subject should be multiplied, and with pickles differing in strength and quality. In the last edition of Deane's New England Farmer, it is observed that "to a bed fifty feet by six, a bushel of salt may be applied with good effect before the plants start in the spring."

Asparagus is reputed to be a very healthy vegetable. Loudon says, in Paris it is much resorted to by the sedentary operative classes, when they are troubled with symptoms of gravel or stone. *Willrich's Domestic Encyclopedia* observes, "Asparagus is allowed to promote appetite; and affords a delicious article of nourishment to the invalid and valetudinary, who is not troubled with flatulency."

RURAL ECONOMY.

(From Proceedings of the N. Y. State Agricul. Society.)

SHEEP HUSBANDRY.

Hosick, Rensselaer Co. N. Y. Dec. 31, 1832.

The breeding of fine woolled sheep has become an important branch in agriculture and industry. Many writers have written very ably on the subject, and much useful and interesting information has been circulated. It might therefore seem presumptive in me, to say any thing more on the subject, had not circumstances given it a new view, and if this branch of agriculture, like every other, were not continually advancing to improvement. The growing of fine wool shews itself certainly in a different point of view than when merinos were first introduced, and even but a few years ago. During some years this branch of industry combated many difficulties; prejudice and the old routine were predominant with the farmer. It was also thought that this country would not admit of raising the finest kind of wool; but at present the intelligent and observing farmer is otherwise convinced. And the period has arrived, when the utmost attention ought to be paid to the quality as well as to the quantity, and produce that kind of wool of which the country is immeasurable deficient, but towards the supplying of which it is making rapid strides. I will not go into an examination of the motives which caused a part of the wool-growers to improve the carcass and heft of fleece more than fineness and quality. Many owners of flocks undoubtedly have not a clear conception of the condition in which the wool business is at present, and the aim after which they ought to strive. It would be vain to depend for the prosperity of their flocks on the measures of the general government alone: These may be ever so wise, and executed with the strictest attention, but they would be without much effect if the wool-grower has not a right idea of his own business.

The study of wool has not received that attention which it merits. Many breeders of sheep managed their flocks by chance, any how. But it must be confessed, however, that many manufacturers showed a sort of indifference as to the quality of the wool, and wool-growers receiving their opinions fell into the same error—prompted, probably, by a temporary profit. However, the manufacturers have, in the path of accomplishment, made advances every year; and the more the art of manufacturing improves, the more skill they get in judging of the raw material they use. For the mean time the producer should keep pace with the manufacturer, as it in my opinion can but improve their condition; as they will not be liable to be imposed upon much by the purchaser, if they know the relative affinities and qualities of their own wool. And let me here remark, that in my opinion, founded on my own experience, this country is well calculated to raise fine wool; and is far superior to it than Germany, and even Saxony herself, where it is well known the finest wool is raised. All the requisites for raising fine wool are bountifully supplied. Healthy and sweet pastures, pure water and a pure air, are elements in which sheep delight. If we only do our duty and manage our flocks as we ought, success is almost certain.

The study of fine wool and management of sheep, has been an interesting employment to me, and much time have I devoted to these interesting animals. Having had opportunities to acquaint myself with the mode of managing sheep in Germany, and for the last five years having kept a flock of full blooded Saxon sheep in this country, I will submit a few remarks

ON THE FEEDING AND CARE OF SHEEP.

1st. *Of summer feeding.*—This consists generally in pasturing. For particular local situations it would be advisable to keep them in the yard, as is the case with some flocks in Saxony, and feed them with green clover, lucerne, esparcette,* or vetches and horse beans sowed together, and fed in racks. Pastures ought to be free of boggy and marshy places—in general more dry than wet is indispensably necessary, for the grass and other plants which grow in such places, even should they become dry by continued dry weather and the heat of the sun, is extremely injurious, as it causes relaxation in the organization of the sheep, which cannot perform the functions of secretion, and the most fatal disease, the rot, will follow.

By what is said above it follows, that pasture seeded with herdsgrass, clover, &c. turnip fields especially sown for that purpose, stubble fields and hilly pastures, are well adapted and healthy for sheep; but the main condition is that such pastures be not wet, and afford sufficient nourishment. The old maxim, that sheep will not eat bad grass as long as they can satisfy their appetites on good, holds true here: they shun or avoid places where unhealthy grass grows by instinct. Enough healthy nourishment therefore is the best remedy for sheep against eating bad plants.

Next to the above requisites, pure water, with which the animals may slake their thirst, is an important object to the animals. Where they have access to water once or twice a day, they will never drink too much and hurt themselves, but where they are debarred from it, by prejudice or otherwise, they are apt to drink of the first puddle they come to, and infallibly hurt themselves; whereby, probably, the old prejudice arose, that water is hurtful to sheep to drink.

For the reason that wet grass, eaten in duration, is detrimental to the health of sheep, farmers in Germany do not let their flocks go to pasture in the morning till the dew is almost off the grass. If by continued wet weather it cannot be avoided to pasture on wet grass, a foddering of dry fodder, if but of straw, is very useful and necessary, together with a mixture of juniper berries and other aromatic herbs and salt

* American Farmer, vol. xiii. page 341.

* Sanfoin.

once a month. Latterly I have found tar to answer as good a purpose. These are not only useful but necessary provisions to preserve the organs of the whole system against relaxation, arising from protracted wet pasture.

2d. *Of winter feeding.*—To the keeping of sheep during the foddering season, is good hay from dry meadows, well cured clover cut when in full blow, lucerne, &c.; all kinds of roots, such as potatoes, turnips, carrots, mangel wurzel, &c. are also beneficial and serviceable. One needs only by regular feeding, proportion the quantity to their nourishment, to suspend the feeding of grain altogether; but when the raising of roots is not attended to, some grain ought to be fed, especially to lambs.

In respect to feeding, it is generally acknowledged that the quantity and quality ought to be adequate to the nature and economy of the animal, to keep it in good and thriving condition, bordering on being rather fat without going over to fatness. It cannot be denied that fatness stimulates sheep and disposes them to sickness. Leanness, when occasioned by too little nourishment, on the contrary, causes weakness and disposes to sickness, besides such animals shearing less wool. He who cannot maintain his sheep vigorous, or is not disposed to do so through ill advised economy, may not expect to make his fortune by fine sheep.

Periodical changes between abundant and too little nourishment, is not less detrimental. It endangers health and strength, or both may severely suffer, and the wool grow uneven and thus become reduced in value. It cannot be understood, however, that ewes rearing lambs, and rams during the rutting season, ought not to be better fed than without these circumstances; on the contrary, it is necessary to give them more nourishment, since there is more chyle and strength wasted.

In respect to the effect of grain, roots and hay upon the increase of flesh, wool and tallow of fine sheep, we are indebted to M. de Raumer, for his experiments, which throw much light upon the subject, and whose results are the more credible since they are in accordance with the experience of others. I communicate his results because they may be considered as a sure basis in this matter.

	Increase of weight in the living animal.	Produced wool.	Produced tallow.
	lbs.	lb. oz.	lb. oz.
1000 lbs. Potatoes, raw, with salt,	46½	6 8½	12 5½
1000 " do. without salt,	44	6 8	10 14½
1000 " Mangel wurzel, raw,	38½	5 3½	6 5½
1000 " Pease,	13½	11 11	11 6
1000 " Wheat,	155	13 13½	59 9
1000 " Rye, with salt,	90	13 14½	35 11
1000 " do. without salt,	133	12 10½	43 8½
1000 " do. meal, wet,	129	13 6½	17 7½
1000 " Barley,	136	11 6½	60 1
1000 " Oats,	146	9 12	12 8
1000 " Buckwheat,	120	10 4½	33 8
1000 " Good hay,	58	7 10½	12 14
1000 " Hay with straw, without other fodder,	31	15 8	6 11
1000 " Whiskey-still grains or wash,	35	6 1	4 0

Potatoes, raw and cut into slices, sheep ate with good appetite and greediness in duration—one sheep ate daily 7 lbs. with straw interchangeably after the potatoes, they remained lively and healthy, and drank 1½ quarts of water per head in 24 hours.

Mangel wurzel, sheep ate with greediness, 8 lbs. per head daily in duration, interchangeably with straw as with potatoes; they drank 1 quart of water per head in 24 hours, and remained likewise healthy.

Pease, 2 lbs. per head daily readily eaten in duration; drank from 2 to 3 quarts of water per head in 24

hours, and remained perfectly healthy. In an unsoaked condition pease are hard for sheep to eat and wear their teeth.

Wheat, sheep ate greedily 2 lbs. per head in duration, and drank from 2 to 3 quarts of water in 24 hours; made them very lively, and remained perfectly healthy.

Rye, sheep do not eat readily, and it does them little good, as is exhibited in the above results of the increase of weight; they drank from 2 to 3 quarts of water daily.

Barley, 2½ lbs. per head daily in duration with greediness, and sheep do extremely well on it; they drank 3 quarts of water per head in 24 hours.

Oats, had the same effect as barley upon the appetite and health.

Buckwheat, sheep eat with great avidity, and with the best results upon the health and liveliness of the animals.

Good hay, 4½ lbs. per head daily in duration, and drank 2½ to 3 quarts of water in 24 hours.

Flag hay, rush, &c. the lighter and the less sheep eat of it the better, as it make them weak and inactive; and two of the sheep on which the experiments were made, became sick—one was killed, the liver and gall of which were found infected, and the other died.

M. de Raumer also considers, in accordance with M. Von Thaur,

- 1 lb. oil cake meal to be as nutritious as 2 lbs. of hay.
- 80 " clover hay, like 100 lbs. ordinary hay.
- 84 " vetches, exparsette and lucerne, the same.
- 200 " good sound straw of pease and vetches like 100 lbs. hay.
- 300 " barley and oat straw like 100 lbs. hay.
- 400 " wheat straw like 100 lbs. hay.
- 100 " turnips nourish as much as 40 lbs. potatoes or 50 lbs. mangel wurzel.

The above I have for a number of years, say 12 or 13, taken as my guide in foddering sheep, and have found that my flock did extremely well whenever I proportioned their food according to nutritiousness, and in such manner as that 2 lbs. of good hay would give to each animal. It, therefore, I fed potatoes or other roots or grain, I gave straw with it in order to fill the belly. The best way I have found to be, a foddering of straw in the morning before roots. It seems to be congenial to the nature and economy of the sheep, and digests better than roots on an empty stomach. This practice is pursued by the most intelligent breeders of sheep in Germany.

Shelter against the inclemency of the weather is the third consideration in the care of sheep. It is almost as necessary to the health and good condition of the sheep as food itself, and for this reason stables built for that purpose are of great benefit. Not only do sheep do much better, but it is also a great saving of fodder and manure. The latter is as important as the former; for manure, properly applied, is money to the farmer—and it is well known that sheep manure is of the best kind. These stables ought to be so constructed as to admit of great quantity of hay being put over head; and for this reason I would recommend a side hill facing the south, and a dry spot around it, for their location. Each full grown sheep requires six square feet including racks. These ought to be so constructed as to have a manger attached to each, for the purpose of feeding grain and roots, and to catch the hay the sheep draw through the racks. The stables ought to be eight feet high at least, nine feet is preferable, and sufficiently ventilated. It is also necessary to have windows for the purpose of light. The difference between wool grown in a dark and light stable is really surprising. In a dark one,

The clover in Germany is finer than that in this state—resembling more the Pennsylvania clover. It is cut when in full blow and well cured in small cocks. If clover is spread it loses a considerable share of the leaves, which reduces it in goodness.

wool does not get the brightness it has in a light one. Of this fact I have witnessed the most surprising proof. Over head the stable ought to be tight, that no fodder, chaff, &c. may fall into the wool, which reduces it in value. The stables ought to be littered with straw from time to time, to keep the wool clean and add to the comfort and health of the animals.

In the foregoing pages I have given, in an imperfect manner, (not understanding the English language correctly,) a few hints on the care and management of sheep. Should they be of any benefit to my brother farmers, the writer will consider himself amply paid.

HENRY D. GROVE.

JESSE BUEL, Esq. Cor. Sec'y.

(This gentleman has been familiar with the management of sheep from early youth, in a country which excels in fine wool. His management of them here has hitherto been uncommonly successful, not losing one in a hundred. I am informed, during a winter. No sheep farmer can fail to derive advantage from a visit to this intelligent and unassuming foreigner.—J. B.]

(From the New England Farmer.)

SWINE.

MR. EDITOR,—I observe in your paper of the 20th of March, a request for information how to prevent swine from devouring their young. I have heard my neighbors make complaints on this subject this season—and believe others have been induced, year after year, to pour forth similar lamentations in the New England Farmer.

But, sir, I believe the difficulty rests more frequently with the farmers than with the grunTERS. Only imagine, Mr. Editor, the poor animal in the "most delicate circumstances," on looking about for a comfortable place to perform her *accouchement* finding only a cold bed of mud, or a desolate pen, perhaps with, and perhaps without a covering, and the thermometer at zero! Or perhaps the considerate owner has thrown into one of these dreary abodes a huge bundle of straw, thinking "nature will do the rest"—and the old sow will soon arrange it into a suitable bed for her young, and then ask yourself—can even a hog, in such a place, do justice to her anticipated charge? The truth is, there is no animal so abused as this despised quadruped—the Jewish law, which forbade their use, was doubtless promulgated by Moses out of pure humanity. And when it was repealed by a christian code, it would have been well had a clause been inserted that "no man should keep hogs who would not take care of them."

No animal in the farmer's possession more completely reflects the character of the owner. If well fed, kept warm, and clean—they thrive, grow and fatten; but neglected, they are ill-shapen, mean, dirty brutes—and the whole farm is disturbed at night and by day by their squealing, fighting, and breaking out of bounds.

One gets a warm place in the southeast corner of their comfortless pen, another stronger comes in and demands possession, a battle begins—the weaker is ousted, and so the night is spent in continual conflict; for without, a strong northwester soon admonishes them, that in exercise, though in battle dire, is their only hope of obtaining a *modicum* of caloric.

But now the farmer discovers that it is necessary for family purposes that the hogs should be parted, and a few old rails are run across the bed-room, to accommodate the hopeful mother. The northwester finds a clear course over the backs of the others, and injects its merciless shafts upon the tenant of the private apartment, and the fresh straw is in vain mouthed about the house in the expectation of a spot being found fit for the interesting deposit. But there can be no more delay, and the little grunTERS come forth! Old Boreas spares not, and is greeted by a most piteous squeal. The nervous mother (no wonder she is seized with hysterical irritability,) takes alarm, and true to nature starts up, and in resewing

her progeny from seeming danger treads on the little squeaker, ends his mortal sufferings, and takes one roaster from the farmer's market cart; another follows—and another—and so on to the end of the chapter. The "poor, forlorn, afflicted, desolate" now consoles herself, the only way she can, by enjoying for once a good repast, not the less palatable for being of her *own flesh and blood*. Then follow the lamentations; and learned disquisitions are sent for insertion in your columns, and "powdered charcoal," "animal food," "corn meal," and "milk porridge," are recommended to cure the *unnatural appetite!* and if they are faithfully administered, "in season and out of season," that is every day, I will answer for it, you will have less lamentation and more pork.

Of one of the neighbors alluded to, who made the complaint to me of "his breed of hogs being run out," for they eat up their pigs—I asked in which pen he kept his sows? (for I knew all about his premises) and he answered "in the pen by the wall in the lane." And it is just such a place, Mr. Editor, as I have described. On the north, an open, single wall, on the south a barn too near to let a winter's sun approach more than a few hours in the day, and on the west a few old boards, just enough to keep the store pigs from "hiring lodgings" in the finished apartments; and the southeast corner, just the one that *might be open*, is the only one closed. I did not wonder his pigs had "run out," I only pitied them that they could not *run away*.

Now, sir, I'll tell you my method, for when trusting to others I have had "pigs eaten up" in abundance, but I look to them now myself, and after keeping them all the time in good flesh, when the period of yearning is near I take the sow apart and give her free access to a *warm bed-room* of ample dimensions in my barn, with a *dry plank floor*, where the shingled walls prevent the entrance of cold, rain or wind, with just enough straw to amuse her "moments of anxiety," but not enough to allow a single pig to cover his head and lose his road to the fountain of comfort. And I have now running about my yard as fine a litter of roasters, just four weeks old, as ever graced Boston market.

I shall be very happy if I have been able to throw any light upon the mysterious science of raising pigs in the winter (for whether summer or winter I find the same result with my *new invention*) for the benefit of your "Constant reader,"—and remain, your humble servant,

ANOTHER.

(From the New England Farmer.)

SWINE.

MR. FESSENDEN: Milton, March 23, 1833.

Sir,—In answer to "*A Constant Reader*" on the best method of managing sows with pigs—I would recommend the following method which I have practised with good success.

Separate the sow from the rest of the swine, six or eight weeks before her bringing forth, so that she may become accustomed to her pen. Care should be taken, however, to have her pen kept dry, and well littered; always give them litter enough so as not to be obliged to give any for six days before the time, for nothing disturbs the sow more than an abundance of litter, and which, in my opinion, has a great tendency to induce her to destroy her young. If the sow is with the other swine till within a few days of her bringing forth, and then separated, she will not get accustomed to her pen, and by thus being disturbed, she will be pretty sure to destroy her pigs.

I do not think there is any thing in the breed or nature of sows, unless disturbed or mismanaged, and if so I think it very natural for them to destroy their young.

I have known, and it is not at all uncommon for young sows to destroy their first, and protect their succeeding litters; and I have known them to protect their first and destroy their succeeding litters; but in

most cases I find that it is owing to disturbance or mismanagement.

Raw salt pork cut in small pieces, and given, will prevent them from eating their pigs. I have seen it given after they had ate two or three of their litter, with good success. But to prevent any mischief it should be kept by them at this time.

As to the form of the sty, and higness of the yard to be occupied by swine for manure, these depend greatly upon the number kept. For three or four I would recommend a building of the following dimensions, say eighteen by eight, entrance to feed, at the centre on the side, alley three feet wide, window in the centre opposite the door, two troughs, one on each side next to the alley, yard twenty feet square, will have a partition through the centre from the centre of the building, entrance for the swine on each side, one foot from the alley with sliding doors, communication from one yard to the other by sliding door next to the building. A building and yard thus constructed will be found plenty large, and very convenient; you have plenty of room at each end to feed, and for them to lie dry and warm, which is very beneficial in the growth of your swine. I consider a yard of the above size plenty large enough for three or four swine, if properly attended to, they will make but little manure without materials, you should replenish the yard with loam or wash from the road, with vines, weeds, &c. as often as occasion may require.

Yours, respectfully,

D.

(From the New England Farmer.)

SWINE.

MR. FESSENDEN:

In your paper I observed an inquiry in relation to the best method of treating sows with pigs, &c.—Neither the "Farmer's Assistant," nor "Bannister's Husbandry," nor the "Hon. O. Piske," have hit the right nail on the head. For some cause, or on some account, whether from "hysteric irritability" I know not, but so it is that about the time of sows' yearning they have a great craving for animal food—this I know from experience, and have been careful for about a week before my sows were about to farrow, to give them some butcher's refuse meat, which does not cost much; it easy to be procured give them a plenty, and I will venture to say they will not eat their pigs.—Your inquirer says thousands of pigs have been destroyed the last year by sows. Now if my method of treatment is a preventive, and I verily believe it is, the information is of more real worth to the community than a history of all the snipes, owls and bob-links that Mr. Audubon ever heard of.

A SUBSCRIBER.

(From the Maine Farmer.)

TO RELIEVE CHOKED CATTLE.

MR. HOLMES:

It is agreed, both in Europe and this country, that there is nothing so safe and efficacious for a creature that is choked, as tarred rope of proper dimensions, with the tar well worked in to stiffen it when made. I have been led to remind my brother farmers of this simple thing, because one of my neighbors recently lost a cow by being choked, and another came near losing a valuable ox, in the same way. Both of them might have been relieved in a few minutes, had such a rope been at hand, or even in the neighborhood, but this was not the case, and the owner of the cow used an improper stick, which hastened her death. I believe we shall more frequently see the need of such an apparatus or instrument, as we begin to feed more with roots. In Great Britain, where they feed extensively with roots, the farmer who was without one would be considered a very careless man.

I hope some one at least in every neighborhood will procure one or two of the following dimensions. One suitable for applying should be three quarters of an

inch thick, and forty inches long, with a strong loop affixed to the end, that it may be the better managed by the operator. For an ox of a large size it should be an inch thick, forty-eight inches long, exclusive of the loop. The cost may be twenty-five or thirty cents.

Yours, &c.

CARE.

(From the New England Farmer.)

RATS—a singular fact.—Mr. Elkanah Andrews, of Taunton, planted the last year, a field with corn in drills, at some little distance from any building or wall, and say about one-fourth of a mile from the village. After the corn came up he found that much of it was pulled up by some animal, but by what kind he could not determine. Some said that it might be done by squirrels; but no squirrels were seen about the premises. Others thought that the mischief was done by birds; but no birds were seen near the place. The work of destruction went on night after night, and it was supposed that the injury was done very early in the morning, and hence the depredator eluded the observation of the owner. Mr. Andrews visited his field very early in the morning, but made no discovery; no squirrel nor bird was seen, yet the corn was pulled up as before. At last he visited his field at midnight, and having secreted himself, he by the help of moonlight discovered his enemy—an army of rats from the village.

(From the New England Farmer.)

FENCES.

As soon as practicable put your fences in thorough repair. Poor fences may be numbered among the worst of bad things, saving Canada thistles, which can encumber a farm. In consequence of low, frail and tottering fences, cattle acquire a habit of wandering, and become turbulent as a gang of highwaymen. A farmer with poor fences can no more sleep quietly, than if he "were pillowed on clouds and cradled in a storm."

The kinds of fence in most general use in this country are post and rail fence, Stone wall, log fence, worm fence or Virginia fence, and hedge fence. These should vary according to difference of soils, plenty and cheapness of materials, &c. Mr. Preston of Stockport, Pa. recommends setting posts with the top part in the ground; and asserts they will, in that position last three or four times as long as when they are set with the butt ends down. He also advises in making post and rail fences always to place the rails with the heart side up. The posts should be set at least two feet in the ground. If those parts of the post, which are to be placed in the ground are burned in a hot fire till quite black they will last much longer than they would otherwise. It has been found useful to cut posts so long and mortise them in such a manner that when the lower ends become rotten they can be turned upside down.

The Farmer's Guide says, "Post and rail fences and board fences are very good when the soil is dry. In a wet soil the posts will be moved by frosts. Red cedar, locust, and chestnut, are best. Butternut, black walnut and oak are pretty good, lasting about fifteen years. For the rails, cedar is best, lasting perhaps an age. If timber is scarce, and the ground is level and free from stones, post and rail fences set in a bank made of the earth of two small ditches thrown up together ought to be preferred. If the posts are too small to have holes made through them, the rails may be flattened at the ends, and fastened to the posts with spikes, or with wooden pins well secured." It has sometimes been the practice to set rows of trees 10 or 12 feet asunder, and insert cedar rails into the trees, the latter serving as posts.

When ground is wholly subdued, and the stumps of its original growth of trees quite rotted out, stone walls, properly made are the best and cheapest fences. On a hard sandy or gravelly bottom a wall will stand many years without repairing. On a clay

or miry soil, the foundation should be laid in a trench, nearly as low as the earth freezes. But a wall of flat or square shaped stones, will stand tolerably on any soil on the surface.

FINE MALTESE JACK FOR SALE.

The Subscriber has for sale (on commission) a fine Jack of the breed of the Knight of Malta and Royal Gift. He is six years old, a very powerful animal, a sure foal getter, very gentle and easily managed. Price \$200, delivered in Baltimore. The following are the dimensions of the animal furnished by the owner:

- 4 feet 2 inches in height, (12½ hands)
- 5 " 10 " round the body.
- 3 " 6 " round the neck.
- 1 " 4 " round above the knee.
- 1 " 0 " round the knee.

Apply to I. I. HITCHCOCK,
American Farmer Office and Seed Store.

SILKWORM EGGS

For sale at the American Farmer Office and Seed Store, at \$1 per thousand. They can be sent safely by mail if ordered immediately, before the weather becomes warm.

I. I. HITCHCOCK.

WHITE MULBERRY SEED, &c.

Just received at the American Farmer Office and Seed Store a supply of fresh and genuine WHITE MULBERRY SEED. Also

MAMMOTH PUMPKIN SEED.

EARLIEST FRENCH CABBAGE do.

PUBLIC SALE OF DURHAM SHORTHORNED CATTLE AND HIGHLY IMPROVED SHEEP.

Will be sold on Wednesday, 29th day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd, the highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEIFERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young Lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand.

DAVID MEADE, Administrator.

April 5,—8t

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals,—viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	300
Do 2 " " Do "	250

ORCHARD AND HERDS GRASS SEED

For sale at the American Farmer Office and Seed Store, by I. I. HITCHCOCK.

Clean Orchard Grass Seed \$3 per bushel. A lot of this seed imperfectly cleaned will be sold at \$2.50 per bushel. Herds, \$1 per bushel.

200,000 WHITE MULBERRY TREES.

The Subscriber has on hand and for sale 200,000 White Mulberry Trees of two and three years' growth, which have been transplanted, are in a healthy and thrifty condition, and which he offers for sale at \$1.50 and \$2.00 per hundred, delivered at the nursery.

Also, a few of the *Morus Multicaulis*, or Chinese White Mulberry.

ASA BUTLER,

Suffield, Connecticut.

P. S. All orders (post paid) will be punctually attended to. April 12,—6t.

FIELD AND GARDEN SEEDS, &c.

J. S. EASTMAN offers the following Seeds for sale, viz. CLOVER, TIMOTHY, MEADOW OAT GRASS, MILLET, LUCERNE, COW PEAS, LARGE YELLOW PUMPKIN, and EARLY WHITE CORN.

Also a general assortment of GARDEN SEEDS, and WHITE ONION SETS.

Likewise in store, a general assortment of AGRICULTURAL IMPLEMENTS, embracing almost every article in the farming line, which he will sell low for cash or approved city acceptances.

He must decline opening any new accounts, except with those who will be liberal customers, and can give good references; and all such accounts he expects to be promptly settled once a year; and those who have accounts standing on his books over one year, are desired to settle the same. All Grass Seeds must be considered cash. Liberal discounts will be made on all implements purchased by merchants and others to sell again.

Feb. 15.

SINCLAIR AND MOORES NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Bushes, (among which is the much admired *Grevillea*.) double *Altheas*, *Honeysuckles*, *Corcorus*, *Lilac*, *Snowberry* and *Buffalo Berry Trees*, (*Chinese Alanthus*, white flowering *Horsechestnut*, and silver leaved *Maple*, all of large size, (the latter is a beautiful shade tree,) large red and white *Dutch Currant*, red and white *Antwerp* and other *Raspberry Bushes*, *Strawberry Plants* assorted, (large plants raised carefully for sale,) white and black *Walnut*, *Quinces* assorted, *Peach Trees*, a large stock of very superior kinds, *Apple*, *Plum*, *Pear*, *Cherry* and *Neetarine Trees*, *Grape Plants* and *Cuttings* of several varieties, *Asparagus* and *Hop Roots*, and *Thorns* for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets.

Feb. 22.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—A slight decline will be noticed in the prices of flour and grain. This is owing to the abundant arrivals. Large quantities of corn have been disposed of at rates within our quotations, while none but very prime commands the maximum rate. In flour a fair business is doing at our quotations. The wagon price of Howard street is somewhat unsettled; from \$5.18½ to \$5.25 will probably be near the mark.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 6.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 395 bbls. Md.; 51 bbls. Ohio; 20 bbls. Ken. and 2 bbls. Vir.—total 378 bbls.

GENERAL.

Agricultural and Horticultural Establishment:

COMPRISING,

A Seed and Implement Store, a General Agricultural Agency, and the Office of the AMERICAN FARMER, at No. 16 South Calvert street, Baltimore: in connexion with a Stock and Experimental Farm, Garden and Nursery in the vicinity.

An extra number of the Farmer, containing a prospectus of the "Establishment," and a "Catalogue of Seeds," &c. kept for sale, shall be sent GRATIS to any person who shall by mail or otherwise furnish his address for that purpose.

AGENTS FOR THE FARMER.—All postmasters are requested to act as agents for the Farmer, and to require a strict compliance by subscribers with the terms, especially the third item. They are authorised to retain one dollar for each new subscriber, and ten per cent on all other collections. The list of special agents is published in the Farmer every third week. (Terms next week.)

DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "I. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, APRIL 26, 1833.

ANGORA GOATS—ANGORA CATS.

The following extracts of letters from Commodore Porter to J. S. Skinner, Esq. late editor of the American Farmer, will be read with interest. We do hope that some of our spirited minded men will avail of the opportunity now presented of importing the Angora goat. There are some gentlemen of our acquaintance who could do this for their country without difficulty; and there are very few acts they could perform that would confer upon it a greater benefit, or of the credit of which they could have more reason to be proud.

—Pera, Jan. 19, 1833.

"I believe I have mentioned to you something about the Angora goats, and the beautiful silkiness of their hair, finer even than silk, and softer. It is of that which they make the Cashmere shawls which cannot be equalled by any manufacture of silk. The animal itself is a beautiful and majestic creature, and I think the introduction of it into the United States would be highly advantageous to the interests of the country. In the fine fabrics it (the hair) would supersede the use of silk. And I would, if I were rich enough, spare no expense in introducing the breed into our country—but alas! a *charge des affaires* with an expensive establishment at one of the most expensive courts in the world, finds it not only hard, but actually impossible, to make both ends meet, with a strict economy, amounting to meanness. I am willing to do all I can to promote the interests and improvements of our country, by the introduction of many things, but I have not the means. The converse of the proposition of the apothecary, in Romeo and Juliet, will suit my case.

"However, as I cannot send you the animal for the want of means, I shall send you a skin, and that alone has cost me five dollars. Then judge what it would cost, to send a person expressly to Angora to purchase and bring the animals to me, to bribe the Mussulim to let them come *unaltered*, for their departure in a *perfect* state is prohibited; their passage and provisions to the United States, and the pay of the person on board to take care of them. All this you may readily conceive would be no trifling affair, yet *coûte qui coûte*, were I able, I would send three or four pair home, and have them placed in different sections of the country to propagate.

"For fear of the miscarriage of the skin, I send you a specimen of the hair, here is a beautiful substance, finer and infinitely stronger than the finest and strongest silk, growing on the back of a hardy animal, the cost of the keeping of which is nothing compared to the cost of keeping a sheep—and the value of the produce per pound, is as superior to silk, as silk is to the wool of the merino. The value of a Cashmere shawl here, is from three to four and some five hundred dollars. The best of the French silk imitations may be purchased for thirty dollars.

"The cost of the introduction of this animal into the United States, would not be much, for two or three public spirited men of fortune to undertake, it would be nothing compared to the expense they were at, in introducing the rotten, mangy, short lived merino.

"The goat is a hardy animal, long lived and subject to none of the diseases of the sheep. You may, by the skin I send you, form some judgment of what the fleece would be worth, even at the price of silk—but I assure you that an Angora goat of the *neuter gender*, now in my back yard, has a fleece of double the length of the fleece I send you.

"The French, you know, were at great expense in

sending out Mr. Jobert to obtain the breed. What they have done with it, or whether it was genuine, I know not; but the breed can be had genuine, funds only are necessary; for my services, you know, are always ready, whenever I can do any thing which may be likely to prove beneficial to the country."

ELECTRICAL PROPERTY OF THE ANGORA CAT.

DEAR SKINNER:

Pera, Jan. 22, 1833.

I last evening made what to me was a great discovery.

I had often seen the electric sparks fly off from the back of a cat, while stroking it with the hand in the dark, but never before felt the electric shock.

I was playing with my Angora cat, it was lying on the table on its right side; I laid my left hand open on its neck, my thumb on the hind part of the shoulder joint and stroked down the hair with the right hand. I felt several very smart shocks of electricity which evidently gave great pain to the cat, as they did to me.

I mention this to you, that other experiments may be made, and if electricity is beneficial in some diseases, (as it is said to be,) I feel confident that it may be obtained from the cat, sufficiently strong for all medical purposes.

At the time this was discovered the weather was dry and frosty, and the room warm.

I caused some of the servants to place their hands as I had placed mine, while I stroked down the hair of the cat, and they complained that the shocks were very painful to them. Whether this is peculiar to the Angora cat, and to the *neuter gender*, can be easily ascertained. The most frequent shocks were felt in the little finger, which rested on the root of the left ear—but the severest shocks were felt in the thumb which rested, as before said, on the hind part of the shoulder joint.

I placed my hands in other positions and could produce no shock whatever.

If this is a new discovery it is worth following up. It may be as old as the hills for what I know, but I never heard of it. Yours truly, DAVID PORTER.

J. S. SKINNER, ESQ.

The commodore corrects an error we made in one of his letters last spring, giving a description of a beautiful tree, some of the seed of which he sent to Mr. Skinner, (see page 115, vol. 14.) We published it *rare tree*—it should have been *rose tree*.

"* We have noticed an article on the prevention of bots in horses, published in the New England Farmer of the 13th March, and credited to the American Farmer, a very valuable paper published at Baltimore. It is an extract from an article originally published in the third number of this paper, in October last.—We have noticed the circumstance not merely from the vanity of reclaiming the article; but, on looking over our account current with the New England Farmer, we find ourselves so much indebted to that valuable paper, that we feel obliged to avail ourselves of every little payment, though we may never be able to balance the account. We are also the debtors of the American Farmer, but feel assured that that publication is too wealthy, and too magnanimous a creditor, to need or require any thing which is not lawfully its own.—Northern Farmer.

[On referring to our files we find that the article in question was copied by us and duly credited to the "Northern Farmer," on the 2d November, 1832, No. 34, vol. xiv. The New England Farmer doubtless credited it to the American Farmer by mistake.—Ed. Am. Farmer.]

HAWKS TO FRIGHTEN BIRDS.—A hawk, confined in a cage and placed in the garden or field, is found to be of more service to frighten away birds than other scare-crows, including a sleepy boy.—London's Gardener's Magazine.

WINSHIPS' NURSERY.—We have just inspected the catalogue recently published by the Messrs. Winships, Brighton. It comprises a list of fruit and forest trees, shrubs and flowers, for sale at their nursery, among which are 120 apples, 120 pears, 88 peaches, 54 plums, 18 apricots, 39 grapes, and numerous varieties of apricots, nectarines, quinces, figs, almonds, mulberries, raspberries, gooseberries, strawberries, and currants. The names of ornamental forest trees, ornamental shrubs, evergreens, vines and creepers, and honeysuckles, fills about ten pages. Of roses, there are no less than 288 varieties, besides those placed in separate classes as Scotch and China roses, of which there are 61 Scotch and 25 China. To this magnificent assortment of roses succeeds 41 varieties of the pæony—a brilliant collection, furnished by their friend Admiral Coffin. The collection of carnations, pinks, chrysanthemums, lilies, and herbaceous perennial flowering plants, occupies about a dozen pages of the catalogue. From this abstract it will be seen that agriculturists may find a beautiful supply of the useful and profitable, while ladies and gentlemen of taste can be equally well accommodated in their choice of the mere beautiful and ornamental. The nursery is five miles from Boston, over the Western Avenue—a pleasant ride.—Boston Courier.

(From the New York Farmer.)

PLOUGHING IN HOT DRY WEATHER.

MR. FLEET:

February 11, 1833.

In the fifth volume of the New York Farmer, I have noticed some editorial remarks concerning ploughing and hoeing in the heat of the day. You will observe that the object is not to condense the moisture of the atmosphere. This moisture, in order to afford food to plants, I conceive must be dissolved in caloric. The moment it is condensed it affords little or no support to plants; the circulation of moisture in plants is said to be very similar to that of the arterial and venous circulation in animals, that is, the moisture received by the capillary vessels of the leaves reaches the roots, and little of this moisture ever reaches the earth, but is taken up before it reaches there by the leaves of plants. The moment this is condensed it can no longer enter by the capillary vessels into the vegetable circulation. To plough then in the afternoon, or to place cold bodies in the neighborhood of plants, would be rather injurious than beneficial.—Such are my ideas on this subject, and I remain,

Yours, &c.

R. M. W.

INVENTION AND ECONOMY.—The editor of the Eastern Centinel, says, that an ingenious tavernkeeper, of that borough, has succeeded in the profitable desideratum of making his fire pay for itself, by burning limestone and coal together, in equal parts. The fire must be kindled in the morning with pure coal, but through the day rather more limestone than coal is used. He thus saves several bushels of coal per week and procures several bushels of lime. To all appearance the stoves emit as much caloric as when filled with pure coal—the cylinder was as usual, in a red heat.

COLLAPSE OF THE LUNGS.—Some young children, when they cry, are apt to suffer a collapse of the lungs or, in the language of the parents, "hold their breath." This occasions great alarm to parents, and is a real evil, for it is sometimes with difficulty that the breath can be recovered. The following is an easy and certain remedy: Close the nostrils of the child with the thumb and finger—put your mouth to the child's mouth, and blow smartly. The lungs will be inflated, and the music will recommence in a moment.

* We have seen this specimen and it really deserves all that the Commodore says of it.—Ed. Am. Farmer.

The weight of mud daily carried down the river Ganges is calculated at seventy-four times the weight of the great pyramid of Egypt.

AGRICULTURE.

(From the New England Farmer.)

AN ADDRESS

Delivered at Bridgewater, Nov. 7, 1832, before the Plymouth County Agricultural Society.

By REV. JONATHAN BIGELOW, OF ROCHESTER.

The ultimate design of Agricultural Societies is improvement. With them all else ought to be either subsidiary or subordinate to progress in the art, and improvement in the various methods and products of agriculture. Among the various means which this society has adopted to subserve these objects, is the institution of a public address on the day of anniversary. I regret that the lamented death of the distinguished individual whom you selected for your first orator, has devolved this duty on one but poorly qualified, either by a study of the science, or by practice in the great and difficult art of agriculture, to add any thing to the stock of present knowledge or present improvement. I have thought, however, that perhaps the half hour before us might not be unpleasantly, nor altogether unprofitably spent by noticing, 1st. the moral tendency and effects of agriculture on those engaged in it.

2d. Advert to the fact that agriculture is, and from the nature of the case ever must, to a great extent, be a progressive art and science; advertising also to some points where improvement is still needed.

I shall first notice the moral tendency and effects of agriculture upon those engaged in it. I use the word *moral* here, in its widest latitude of meaning, embracing all effects produced on mind and character.

That occupation it will be conceded is the most favorable to moral development which is attended by the fewest temptations, which furnishes the most salutary lessons of instruction, and which is most favorable to a perfect development of the bodily as well as mental powers. I say bodily as well as mental, because the mind sympathizes with, and in its character, thoughts and sentiments, is very much affected by the body with which it is connected. Probably no mind ever received a full development of all its powers, connected with a physical system deranged; or only partially developed. The various labors of the agriculturist bring all the muscles of the human system into daily action; thus causing a simultaneous development of them. This keeps up that just balance in the system which is indispensable to health, vigor and cheerfulness; and the fact that all his labors are performed in the pure air of heaven, gives tone, energy and durability to the system. The result is that the firmest and most enduring constitutions, the finest modelled forms, and limbs of most nerve and power, must be sought for among an agricultural population. There too, you will find the greenest old age, the most uniform health, the most unaffected and constant cheerfulness and content, as well as the most frequent instances of longevity. Each of the professions and almost all other occupations and pursuits either give an undue exercise to *some muscles*, while they leave others dormant, or else the individuals engaged in them are confined in unwholesome air; either of which is sufficient to lay a foundation for disease and premature old age. If proof were demanded I would refer you to the fact, that while one in forty dies annually in our most healthful cities and manufacturing villages, not more than one in sixty five or seventy die annually in the most healthful agricultural districts.

Agriculture, beyond doubt, is pre-eminently conducive to health, robustness, vigor, energy, cheerfulness and longevity. "But what," you may ask, "has all this to do with the subject—with moral development?" I answer, no one will ask this question who

has suffered years of misery from a deranged system, from feeble nerves—or from any other of the ills incident to sedentary habits, either in the study, at the merchant's desk, on the work bench, or from the unhealthy air and deafening din of a factory. Such will instantly recall their own experience, and by it will be convinced that a healthful mind cannot exist in a diseased body; that a mind brave as Cæsar's, must be united to a body as robust and enduring as was Cæsar's; else when the spirit begins to burn and brace up itself to brave danger, it will find the flesh cowardly. Courage, fortitude, decision and energy are incompatible with, and never exist in perfection except in minds united with bodies fully, harmoniously and healthfully developed.

Moreover, agriculture is not only pre-eminently favorable to moral development by training for the mind a body thoroughly adapted to all its wants, ready to second and execute all its purposes, and capable also of enduring its most powerful and long continued efforts; it is also pre-eminently favorable, by presenting to the mind an endless variety of topics of thought and objects for examination. The agriculturist has to do with nature in all her variety of productions, in all her diversities of soil, in all her processes of vegetation. The atmosphere with all its changes, the seasons in all their alternations, are constantly soliciting his attention. His companions in the field, are the gay songsters revelling in all the luxuriance of life and joy. He is constantly associated with nature in all her richness of beauty, loveliness, purity, majesty and cheerfulness; he has therefore the best opportunity for studying nature in all her processes and in all her productions both animal and vegetable; not in books which often are but mutilated copies or bad translations, but in the original. He stands at the fountain—at the spring-head, and drinks, or may drink the waters of knowledge fresh bubbling from their hidden source. He lives and moves and breathes, not among the images and creations of poetry, but in the sacred temple where the realities are enshrined, of which poetry in its sublimest, sweetest, most melting, or most spirit-stirring numbers is only a poor description—a temple whose lofty arch is filled with the wonders and lighted up with the glories of its author, and whose apartments are all filled with the stores of his goodness and his love.

And moreover, the agriculturist has inducements greater than any other can have, to listen to and ponder the instructions which nature presents to every sense, to awaken indeed every sense to drink in her beautiful, melodious, odoriferous and palatable, and not less useful than palatable, instructions. His interest demands it, his success demands it, his happiness demands it. He cannot be an adept either in the art or science of agriculture without it. That, which curiosity or amusement prompts others to examine, profit requires him thoroughly to investigate, and what is not less favorable, his subjects can never be exhausted. Every repeated investigation presents some new wonder. On the other hand, the mechanic, the machinist, the manufacturer, the merchant, are confined by their employment to a comparatively few objects—the properties, parts and powers of which, as far as his employment demands, are soon learned, and the principal effort which the mind is afterward required to make, is the acquisition of skill in execution.

Further, agriculture is pre-eminently favorable to moral development, because it presents fewer temptations than perhaps any other employment. It is said that "every trade has its cheat," and it was a maxim esteemed by the ancients worthy of recording for posterity, that "between buying and selling there sticketh iniquity"—certain it is that there is room for temptation to enter. Agriculture on the other hand does all that can be done to keep the door closed by which temptation enters—it removes the individual from the thronged streets and the haunts of the idle and vicious, and keeps him constantly employed—away

from scenes unfavorable to virtue. Still more, nature is perfectly honest and faithful in all her processes, and he who holds daily communion with her cannot but imbibe her spirit. The vending of the products of agriculture, as well as their cultivation, does not admit of much deception. The articles cannot be made to speak more than the truth, so that the agriculturist is obliged to form the habit of honesty and fair dealing.

Agriculture is also the parent and nurturer of patriotism; not that patriotism which vaunteth itself, while it all the while seeks its own, but that patriotism which leaves the plough midway the furrow, seizes the sword and flies without stopping to change its dress, to the point invaded, and which brings up the rear of the slowly retreating still fighting band, as it reluctantly leaves in the hands of the enemy the battle kill covered with the slain. Or rather, that patriotism which identifies its interest with its country, obeys its call, *rais*s, as well as commands its arms—plans as well as executes, without reward—delivers its country, raises it to independence, and then, when a crown is within its grasp, spurns it and retires again to the peaceful and pure pursuits of agriculture, as the acme of earthly desire.

We do not mean to say that patriots are not to be found among all classes and engaged in every pursuit. The history of our country proves that patriotism is peculiar to no class and no profession, but we do say, that it is agriculture's legitimate offspring. Agriculture attaches the individual to the soil, locates him, makes him feel that his own interests are indissolubly united with the interests of his country for his property is an integral part of the country. He cannot, as does the merchant, go from city to city, where gain happens to invite, stay so long as profit dictates and flee the moment danger lowers. He is the owner, and he well knows that when the emergency comes, he must be the defender of the soil. His feelings; sentiments, purposes and plans from childhood are formed and fashioned on this supposition; his labors in the field give him the muscular ability, his interest, when all nobler principles fail, give him the inclination and the requisite courage. It will ever be true, that agriculturists are the natural safeguard and defenders of a country, and though they may not be the first "to *scot* the approach of tyranny in every tainted breeze," they will be the first to defend and the last to relinquish their rights, their immunities, and what plain sense dictates to be their country's weal. Like the sated lion in repose, not easily roused, but when aroused, they are like the same lion, when he leapeeth from the jungle and roareth upon his prey. Thus did their enemies find them on the plains of Lexington and on the heights of Charlestown. *These were farmers' battles.*

I might go on to show that agriculture is eminently calculated to nurture all their moral virtues in their genuine simplicity and sincerity, and though it does not give that artificial refinement and grace to manners called politeness, it gives what is more valuable, an open, manly, generous sincerity of manners.

The agricultural arrangements of New England have done more than most are aware towards forming that inexplicable and unique character, which distinguishes New Englandmen and their descendants from all others of the human family, and makes them to foreigners a riddle not easily solved. The bearing of a New England agriculturist is not that of a southern planter, formed by commanding slaves; nor that of the English landholder, formed by "grinding the faces," and receiving the supplications of a dependent tenantry. Nor does the New England day-laborer exhibit any thing of the obsequiousness and servility of spirit manifested by the slave or the tenant. The New England character and spirit were formed, by being both the owner and tiller of the soil: a character which is the result of feeling that the individual is an *equal among equals*, combining in it necessarily all the elements of liberty and self-government.

* Calvin Tilden, Esq. of Hanson.

The agriculturists of a country constitute the parts and parcels of its constitution; not that constitution which is written on parchment, which the winds may blow away, or the fire consume, but that which is before all others, and by which all others consist, and which held the State firm in the hour when charters were abolished and laws were no more. I say agriculturists, for as they feed the body politic and constitute its natural defenders, so their condition gives tone and form to its government. Answer me one question respecting any country, and you answer all others respecting the real nature of the government and the condition of the governed. Who owns the soil? does the sovereign, or is it subject to his direct control? Then the government is a despotism, and the people are slaves. Is the soil owned by the *few* and cultivated by the *many*? The government is an aristocracy; the people have *many* to tyrannize over them. Is the land owned in common? The nation has not emerged from barbarism. Is it parcelled out, as our forefathers parcelled out New England; each family owning the farm it cultivates? The government is essentially a popular government; the people have all the essentials of freedom.—The French laid the corner stone on which the temple of liberty will ultimately rise, not when they altered their constitution and form of government, not when the guillotine became a fountain from which flowed a river of blood, not when they laid the neck of their generous but weak monarch on the block, and chiselled from the Tuilleries the insignia and inscriptions of royalty and proclaimed France a republic, nor yet when they shut the temples of religion in which the ministers of abomination had long ministered and tyrannized, nor yet even when they aimed a bolder stroke and exiled their nobles and nobility from their shores. All these, by a *vote* may be banished, and by a *vote* be restored. They laid it in the hour when the peasantry were declared citizens, when the extensive domains of the king and the exiled nobles were confiscated, cut up into small plantations and sold, so that multitudes who were only tillers, became in addition owners of the soil. A misnamed holy alliance restored the Bourbons, reinstated the nobles, and placed the Jesuits in all the departments of religion, and abolished all that could be abolished of the revolution. One thing alone remained—the soil had changed hands, the manors had become farms, fields, vineyards and hamlets of cottages. Power could compel France to pay for, but found it impossible to restore to the nobility their ancient domains and their tenantry. Henceforth France may have kings, but henceforth there will be no *subjects* there; and I venture to predict that no revolution can make the other nations of Europe free, but one that shall upturn the foundations of its society, that shall make its tenantry citizens, and that shall wrest from the king, the nobles and the ecclesiastics, their domains, and perdit the tiller to become identical with the owner of the soil.

All other measures will be but quack prescriptions for the symptoms, instead of specifics for the disease.

On this subject a volume of deep interest and full of instruction might be written, but those of you who have reflected upon it, need no other proof to convince you that the agricultural arrangements of the non-slave holding states, are the permanent constitution of our country, the charter of our liberties; that which will give tone and shape to our government through all coming time. Yes, as long as these arrangements shall remain unimpaired in the non-slave holding states, (the owner and tiller of the soil being the same,) their sons will sit as now, each under "*his own vine and his own fig-tree*," having none to molest or make afraid," simply because it is his own; and in them, in the end, will you find agriculture attaining its highest point of perfection, and pursued with most profit to the cultivator and the community. Egypt was the granary and Palestine the glory of the world only when cultivated by the owners of the soil.

Thus I have attempted to show that agriculture stands pre-eminent among human pursuits, not only because it is indispensable to individual subsistence and national prosperity, but because also it is pre-eminently conducive to the welfare of those who are engaged in it—it gives harmonious and healthful development to the body; energy, courage, firmness and manliness to the mind; is peculiarly favorable to the formation of virtuous and temperate habits, to the acquisition of knowledge, to the growth of that peculiar property called common sense, to purity and integrity of character. These properties are the foundation and pillars of self-government and rational liberty.

I pass on to notice, briefly, the fact that agriculture is a progressive art and science, and also to notice some points where further improvement may be made, and is needed.

That agriculture is a progressive art and science, is evident to all who have attended to its history, or to the improvements which every year brings along with it, and although some remain, whom neither example nor argument can convince, that the implements of agriculture used and the modes pursued by their grandfathers were not perfect, their number is fast diminishing.—When Lamach, with that inexplicable tide of emotions, known only to a father's heart, embraced his infant first born, having surveyed him with that anxious eye which would fain read in his countenance the initials of his future history, he exclaimed, "Noah, comfort, this same shall comfort us concerning our work and toil of our hands because of the ground which the Lord hath cursed," he saw, or thought he saw in him, a genius for agricultural improvement. From some notices in his history, it is probable that the parent's anticipations were realized, that Noah did greatly improve the agriculture of his age, as we find him planting a vineyard immediately after leaving the ark; and we know also that the plains of Shinar, where he is supposed to have resided, became highly cultivated before his death.—With feelings similar to those of the patriarch would the father of Sir John Sinclair have embraced his infant son, could he have foreseen all the blessings which that son was instrumental in conferring upon agriculturists. His indefatigable efforts resulted in the establishment of the British Board of Agriculture, the first and parent of agricultural associations—"an institution whose services," says an English writer, "cannot be too highly appreciated." It caused farmers residing in different parts of the kingdom to become acquainted with each other, and with the plans and modes of culture adopted by each—caused a rapid dissemination of knowledge among the whole profession—brought the art of agriculture into fashion—amended old practices and introduced new ones—and called forth a degree of effort hitherto unexampled in this island. The impulse given to agriculture in Great Britain by that institution extended across the Atlantic. Some of the sons of America had been there—had employed their native inquisitiveness, and alive to every thing with which profit is connected they transplanted into our own soil a scion from the vine which clustered so thickly with blessings. The formation of agricultural societies in America, has been attended with advantages and results as great if not superior to those in Great Britain. Their publications have extensively circulated important information respecting the best implements, the best modes, and the best products of agriculture.—Their premiums have set in operation the inventive genius of their countrymen, and greatly improved the instruments of agriculture.—Their experiments have convinced the community that agriculture is a progressive, a great, and difficult art.—Something also has been done towards convincing the community that it is also a science as well as an art; and that it is only by calling science to its aid, that it can ever hope to arrive at any thing like perfection, or receive any great improvement, or be reduced to general rules. The application of science to agriculture is a modern

improvement. Ancient agriculturists, both practical and theoretical, were ignorant of those sciences which have a direct bearing upon agriculture, viz. geology, mineralogy, chemistry, botany, and vegetable physiology, or the analysis of plants, and a careful observation of their various natural localities and habitades. All these have a direct bearing upon the art of agriculture, and must be thoroughly understood before the art can be perfected. Until the time shall come when legislatures, or wealthy individuals of enlarged views shall endow seminaries connected with farms, where agriculture shall be taught, both as a science and an art, (which is at this moment the great improvement demanded,) we must look to agricultural societies and scientific and independent agriculturists to call forth and supply this knowledge. We must look to them not only to collect it in masses, but to break it up into morsels and distribute it among the people and illustrate its application by their example.

Agriculture is a progressive art and science, and although its friends may well felicitate themselves that through their instrumentality, its progress for some years past has been so much accelerated, that so many improvements have been introduced, that the art begins in our own country to take among human pursuits the high rank it ever ought to hold, still, let us ever remember the field of improvement has but just been entered upon. A boundless prairie lies before us—its soil is deep and fertile, and will richly reward those individuals or that generation which shall have the enterprise and industry to explore and cultivate it. The implements of agriculture, comparatively excellent as they are, are still susceptible of great improvement. Much remains to be done, before the best breed of animals, the best varieties of vegetables, and the most profitable kinds of grains and grasses shall be universally introduced. From experiments which I have made for the last ten years, on at least thirty varieties of the potato, I am satisfied that every farmer may keep his table well supplied from his own farm with this most valuable of roots, of as good quality and in as great perfection as any the Emerald Isle can produce, without materially increasing the expenses of production. I might make a similar remark respecting fruit trees and the various vines and vegetables of horticulture. The improvement, however, most needed, and one, which if supplied would do much to secure all others, is a place or places where agriculture will be thoroughly taught as a science and an art; where some at least from every town may obtain a *thorough agricultural education*, and become not only channels through which information shall flow, but who shall have all the power of example over their fellow townsmen.

The impression that rests on my own mind is, that we have entered but the outer court of nature's temple; that apartments of surprising splendor remain to reward our research—that science is the only guide that can lead us through and lay open to our view all its sacred recesses. I would say to this society, and all similar institutions, go on and abound in your patriotic labors—raise, if possible, to the highest elevation, the agriculture of your country. Clothe her hills with richest verdure, and make her valleys rejoice, and let the bleating of the flocks mingle in harmony with the murmuring of the rills, and the roaring of the water falls, and the busy hum that comes floating on the breeze from the crowded streets of our cities and villages. It is the true "American system"—the foundation of our prosperity, our liberties, and our government. I pretend not to a prophet's ken, but if I mistake not, the demon of discord and misrule must first subvert the agricultural arrangements of our country, degrade and vitiate its agriculturists, before it can lay the glory of America in the dust. To them, under God, is committed the salvation or destruction of our republic. With their good swords they won it, and by them, when all other means fail, it must be defended, or go down to mingle its dust with the relics of ancient republics. Let us

all remember that the day of harvest is coming, when we shall all reap for good or ill, what in this seed time of our being we have sown—and let us sow only the good seed of honesty, truth, integrity, uprightness and propriety, towards Him who alone can bless our labors, save our country, and prepare our spirits to return to, and mingle again with the bright effulgence of his love, whence they flowed.

(From the Maine Farmer.)

ON THE CULTURE OF POTATOES, &c.

MR. HOLMES:

Wayne, Feb. 1833.

Much has been said and written on the culture of the potato, and several pieces have appeared in your useful paper. I hope, however, not to be thought arrogant if I conclude the subject, not quite exhausted. For years past, I have observed in my fields of potatoes some to come up with a large and thifty stalk or shoots, and others that were small and feeble, and all in the same hill; and when dug, I found as much difference in the potatoes as in the tops, which caused me to bestow some thought on the subject, and I concluded it could not be in the soil, but in the seed. In order to bring the subject to the test, as well as I knew how, I took a parcel of potatoes, all of one sort, the last spring, cut off the seed ends (enough for two rows; the other part of the potato I cut sufficient for two rows more, and planted them side by side, and at the same time; those from the seed end had (as might be supposed) the greatest number of shoots, but much smaller and less vigorous and continued so till harvest. Those from the stem ends produced the largest, fairest, and most in measure, but not the most in number. Fair, good sized potatoes should always be selected for seed, and if the seed end be avoided, I think it the better. As to the best soil for good table potatoes I have no hesitation in saying, that good light, loamy land is the best; a moist, strong soil may, and doubtless will produce the most in quantity. Fresh or green stable manure should never be put into the hill, if used at all, it should be spread and ploughed or harrowed in.

Let it always be remembered, that all kinds of potatoes should be planted early enough to get fully ripe, or you cannot have a good potato. It is of almost as much consequence that a potato should get ripe as any other vegetable. The mode of planting, which I formerly practised was in rows of equal distances and at right angles; say about three feet asunder; which mode was a great loss of ground. My practice for several years last past, has been to plant in straight rows one way about a yard distant, and as nigh the other way as I could with convenience from the hills, by which means I have obtained about a third more on a given quantity of ground. As I intended to write only a few lines, when I began, it is time to hasten to some other observations which I have no recollection of seeing in any publication; I mean the preservation of the potato after it is grown. Potatoes should always remain in the ground as long as possible without being injured by the fall frosts. Many farmers dig their potatoes as soon as the tops are dead, presuming they will grow no more, but the contrary has been sufficiently proved; but if the potatoes do not gain in quantity, they certainly will not lose in quality as they would if dug early. If you wish to spoil good potatoes, give them as much light and air as possible, and you will not be disappointed. If you wish to keep your potatoes sweet and mealy, seclude them as much as possible from both light and air. It is the practice of some farmers to dig a hole in the ground and there deposit as many potatoes as they think they shall want during the next spring and summer; they take them out in spring and find them as good and mealy as they were in the fall. To keep potatoes well, select a corner of your cellar for a bin, board it up on both sides of the studs and fill the space with earth; then cover the top with a layer of green hemlock boughs, see that your cellar win-

dows are shut as soon as you begin to deposit your potatoes, in order to prevent a circulation of air, as much as possible. As much depends on the preservation of potatoes, after they are harvested and in cooking, in order to have good mealy ones, as there is in the seed and culture both put together.

Ladies, as I have been addressing your husbands, it would be a great want of decorum in me to neglect you; therefore, I say, if your husbands furnish you with good potatoes, either by culture or purchase, do not spoil them in cooking. Do you ask how this can be avoided? I answer, never put your potatoes into cold water, but boiling, and keep it boiling until the potatoes are done, or sufficiently boiled; then pour the water off as soon as possible; if a little salt be thrown into the water when boiling, the better.

YEOMAN.

(From the Kennebec Farmer.)

MANNER OF APPLYING MANURE, PLOUGHING, PLANTING, &c.

MR. HOLMES:

Wayne, Feb. 16, 1833.

Sir,—Will you or some other gentleman through the medium of your paper, answer the following questions designed for the benefit of the farmer generally, and which may be the means of sitting at rest various opinions existing thereon.

First. Will manure cause as rapid vegetation, when spread and ploughed in, as when mixed with the soil by harrowing only?

Second. Is it necessary that the old turf be disturbed (provided the furrows lay flat and even,) in cross ploughing?

Third. When furrowing for the hills for corn, should these furrows be deep, or shallow.

Fourth. Should the hills be nearer than, or equal distant with the rows; and in planting potatoes, should the same rules be adopted, exclusively of the manner of manuring the hills?

Fifth. Should the seed of the potato be over or beneath the manure? I have about four acres of ground to plant with corn and potatoes, with a good portion of manure yet to be put upon it; and I wish to understand what method I shall take that will be most advantageous. And I wish to have your opinion as well as others, concerning the ploughing of ground; whether it would not be far better in the end, considering all expenses in so doing, to have every stone removed that shall obstruct the plough previous to ploughing? Some one may say if the gentleman who advances these ideas had some of our rugged farms to deal with he would at once resign his opinion; very true. I admit there are some farms that have but few acres, that might be thus subdued; but with a half acre thus managed, they would acquire more net profit, than with twice the quantity managed in the common way. Some may doubt it. Gentlemen, try for yourselves, and you will have the pleasure of seeing little grass in your cornfields, and in years following, of trudging after your ploughs without seeing the nose from morning till night. The soil would in time become cheaper and therefore would not bind out in half the time. Let reason's perfect balance weigh the whole. Yours, &c. A YOUNG FARMER.

REMARKS BY THE EDITOR.—I. In answer to this question, we think it must depend upon the state of the manure used, and the depth which you cover it by the plough. If the manure has not undergone any fermentation, and it be covered to a moderate depth, when the fermentation commences,—there is a genial warmth kept up during the process or during the first stages of it. This warmth promotes vegetation, but if the manure has been fermented and decomposed before it is applied, vegetation will not be particularly hastened by it; to be sure, it will be promoted because the manure will yield a good supply of food to the plant. On the other hand, if green unfermented manure be buried deeply, the process of fermentation will be proportionally delayed, and consequently any

assistance it can be to hasten vegetation must be small. It will however come into operation later in the season, and be of great benefit to the crop in the latter stages of growth.

2. No, sir. If your turf is well covered, let it lie and ferment; if you turn it back to the surface, more than half of it will dry up, or if it ferments at all, the useful gaseous particles will fly off into the atmosphere, instead of being detained and incorporated with the soil. There can be no profit in manuring the atmosphere,—unless it be to the doctors.

3. Not so deep that the influence of the sun cannot reach the seed and cause it to germinate, nor so shallow that the rains will wash it out, or sun dry it up.

3. Nearer;—but have your rows so situated, and sufficiently distant, to let in a due share of sunshine, as that is an important item in a cornfield. Be sure also that your land is rich enough to support what you put on.

5. We had rather have the manure mixed intimately with the soil, but if it must be put into the hole, we should prefer, as a general rule, to place it below the seed, because, in order to do any good, the manure must decompose or rot. If it does this, there must be given out some gaseous particles; these being lighter than the surrounding matter, have a tendency to rise, and if they rise they will pass through the soil in which the seed is placed, and perhaps come in contact with the roots and fibres of the plant, and stand a chance to become absorbed by them.*

In regard to the query, what management will be most advantageous in regard to his corn crops; we will state one which was suggested to us by a faithful young man, whom we have employed for some years, and which has never failed. The land is a sandy loam,—of good texture, and free from stone. Forty or fifty loads to the acre of common "barn manure," as it is called, is put on and ploughed in deeply. A good coating of unfermented horse dung is then put on, and either harrowed in or covered lightly with the plough. The corn is then manured in the hole with hog manure, and covered a suitable depth. We have not failed of having a good crop since adopting this plan. Our reasons for it are these, viz. The springs in this state are apt to be chilly, and Indian corn requires something to bring it forward. The hog manure being easily decomposed, commences putrefying, and furnishes a warm bed for the corn to germinate in. The horse manure being buried a little deeper, commences putrefying a little later, and continues the warmth; and lastly, toward the close of the season the coarse manure which had been buried deeply "follows suit," and the roots extending down into it, receive the benefit of it at a time when the seed is filling and ripening, and the plant needs a good store of sustenance and support.

In regard to moving stones, we would move every one that was large enough to put into a wall. The space which it takes up to say nothing of the trouble it occasions, would support more or less spires of grass, and spires of grass make tons, you know. Small stones however, if not too numerous, buried in the soil are beneficial to preserve moisture, &c.

NEW ZEALAND SPINACH.—New Zealand Spinach produces fine pot greens in abundance; and the objection to its culture arises from its coming late in the season. This may in a measure be remedied by starting the plants in a hot bed. Twenty plants will afford a daily supply for a family. Near the south of England we are told it has become quite a weed; wherever it is once sown plants rise spontaneously.

B.

*Experiments however have not fully confirmed this theory. Mr. Jesse Putman in stating his method of raising potatoes to the committee of the Essex Co. Ag. Society, says—"with regard to placing the potatoes upon or under the manure, I could see no difference in the yield."

(From the New England Farmer.)

MANGEL WURZEL, OR FIELD BEET.

The species of beet called mangel wurzel is probably one of the best, if not absolutely the most valuable root for field cultivation which modern husbandry has applied to the feeding of cattle. Among its reputed excellences are numbered that of its being a very sure crop, as the plant will endure the driest weather with less injury than most plants, its affording not only a greater quantity of produce, but more nourishment in proportion to its weight than any known root, excepting the potato, and some other varieties of the beet, which do not grow so large nor yield so much to the acre.

The field beet is sometimes called the root of scarcity, but Loudon says it is incorrect to give it that name. "It is supposed by Professor Thaer, to be a mongrel between the red and white beet. It has a much larger bulb than either, and that bulb, in some varieties, grows in great part above ground. It has been a good deal cultivated in Germany and Switzerland, both for its leaves and roots; the leaves are either used as spinach or given to cattle; and the roots are either given to cattle, used in distillation, or for extracting sugar. The variety preferred in Germany is one slightly tinged with red for cattle, and the pale yellow variety for the distillery and sugar manufacture. The seed must not exceed a year old, and great care should be taken that the seed of the common red and white beet are not mixed with it.—The seed of every variety of beet is very apt to degenerate."

SOIL.—The soil in which this root thrives best is a deep, rich loam, inclining to clay. The more the land is manured and cultivated, the better the plants. The soil should be made fine to a good depth.

QUANTITY OF SEED, AND ITS PREPARATION FOR SOWING.—The quantity of seed, according to English writers, is four pounds to an acre. This is said to be rather a large allowance. Some cultivators recommend to prepare the seed for sowing by soaking it for six hours in soft water. This may not be necessary except the land is very dry, at the time of sowing.

TIME AND MANNER OF SOWING.—For field crops the following methods and times have been adopted by successful cultivators. Mr. Gideon Foster in giving an account of his premium crop, raised 1830, says, "Early in May there was spread on an acre of ground about eight cords of compost manure, and ploughed in to the depth of eight inches, and harrowed in the usual way. About the 12th of May, I sowed the seed in rows by hand twenty two inches apart."

A writer with the signature E. D. A. who dates from Southbridge, Conn. in giving an account of a crop of mangel wurzel, which he raised in 1829, says, "the ground, one-fourth of an acre, was ploughed three times last spring, once rather deeper than usual, harrowed and rolled, then furrowed three feet apart; but it ought to have been but two; and about ten loads of compost manure put in the furrow, which was composed of about equal parts of argillaceous [clayey] cleanings of ditches, barnyard and barn window dung, heaped and fermented together. The manure was then covered by ploughing back furrows on the same, leaving the land in high ridges. I then passed a heavy ox roller over the ridges cross-wise, which laid them in gentle swells, and compressed the soil and manure together. (The roller can hardly be dispensed with if you wish your soil reduced to fine tilth, and you cannot reasonably expect to succeed without.) About the 12th of May the land was planted in the following manner—first a wheel made to fit the place of a common wheelbarrow wheel, with pegs, in its circumference about 2½ inches long was run upon the ridges, making holes about four inches apart; and one capsule or berry was dropped in each, and the earth pressed upon them. At the second hoeing, the plants were thinned, and left about eight inches apart in the rows, and were hoed but once afterwards."

SUGAR BEET.—A writer for the New England Farmer, with the signature E. B. whose communication is dated Concord, Mass. Jan. 23, 1830, prefers the sugar beet to the genuine mangel wurzel, and recommends it as "affording a bountiful crop of large sound roots, which, if not so large as the mangel wurzel, I think are heavier, and will keep better. Their use as food by my cows has produced a decided improvement in the quality of their milk, which has been perceptible to all my family, in two days after I began to feed them out to my cows."

John Prince, Esq. of Roxbury, has had much experience in cultivating both the mangel wurzel and sugar beet, and we believe prefers the latter. Its crop is not so bulky, but is not only sweeter and more nutritive but may be preserved with more facility from decay or deterioration.

NEW SPECIES OF POTATO.

The English papers give the following account of a new kind of potato, or a substitute therefor.

"The *Oxalis Crenata* has lately been introduced into this country from South America, and is likely to be extensively cultivated as decidedly preferable to the common potato. A root was brought over, in 1830, by Mr. David Douglas, and planted by Mr. Lambert; and a few small tubers were exhibited to the Linnæan society. One of these was planted by Mrs. Hirst in the garden of Great Koper's Hall, near Brentwood, and has succeeded remarkably well. It was first put into a small pot in the end of April, and in the month of May the pot was placed in the flower garden and broken, and the parts removed. This precaution appears to have been unnecessary, for it has stood the frost remarkably well, and on the 5th of this month, when it was dug up, the leaves were green. The root planted was about half an ounce in weight, and the roots produced were about ninety in number, in a space not exceeding nine inches in diameter and six inches deep. The aggregate weight was upwards of four pounds. A few of the roots were boiled, and when eaten, were found to resemble the potato, but were unanimously admitted by all the party to have a more agreeable flavor. Such a result is very promising, and when we consider that the common potato (*Solanum tuberosum*) was, for a hundred years confined to gardens, and that its roots were for a long time not larger than beans, and were watery, we may reasonably expect that cultivation may do much to enlarge the size of the roots of the *oxalis*, and perhaps improve the flavor beyond what it is at present. It has a fine yellow flower, and is ornamental in the garden. The time of flowering is August. The stems were numerous, large and diffuse; the flowers, slightly notched; hence the epithet *crenata*. At present, the tubers somewhat resemble small kidney potatoes, inclining, however, to grow in an aggregate form."

POTATOES.—A correspondent of the Farmer's Magazine, says he has raised, the last two years, two good crops of the kidney potato on the same ground. In taking up the first crop he buries the tops, or herbage, in the trench by turning the earth between the rows upon them, and this done the ground is ready to be planted again. My first crop last year was planted on the 30th of March, and my second on the 12th of July, the second has been as good as the first, and the potatoes are perfectly ripened; the joint produce of the two crops has been fully at the rate of 960 bushels an acre. I took some of the potatoes of the second crop, of nearly the full size, to market on September the 15th.

POTATO PASTE.—Mash boiled potatoes very fine, and while they are warm add a sufficient quantity of butter and make them boil together; then before the paste gets cold flour the board to prevent it from sticking, and roll it to the thickness wanted.—*Farmer's Reporter.*

HORTICULTURE.

(From the Library of Agricultural and Horticultural Knowledge.)

PLANTING GROUND TO THE GREATEST ADVANTAGE.

A correspondent (Mr. Howden we believe) in the 17th number of the *Gardener's Magazine*, thus describes a very ingenious "plan for planting a piece of ground to the greatest advantage." In the winter of 1814-15, on account of some alterations of roads, plantations, &c. a piece of land dropped into my hands, of an awkward shape for tillage, and rather too small for pasture; I therefore concluded to introduce a little spade husbandry; as the house was pretty near to the farmyard, the intercourse or advantages betwixt them would be reciprocal. Accordingly, having no gardeners, I set farm laborers to make so many ditches, four feet wide, and two feet deep, at every twelve yards, clear across the whole, the turf and good soil were thrown on one side, and the bad soil on the other. The laborers wondered what such ditches could mean, as they were as wide at bottom as at top, and particularly, when I ordered them to be filled up a foot thick with fresh farmyard manure; and the turf, and what little good soil there was, chopped and thrown on the top of the dung. I had prepared a compost of turf and dung the year before, which was laid upon the whole, about nine inches thick, in which I planted fruit trees in the following order:—at every six feet, in the centre of what I now call a border, was planted a standard, then a gooseberry, then a currant, then a dwarf, then a currant, then a gooseberry, then a standard, &c. I was not so particular as some are in my choice of fruit trees; I gave my nurseryman a kind of roving commission, to send me a couple of each of such as he could recommend, then added two, four, six or eight of such as I could recommend myself. On the edges of the borders I planted rows of strawberry plants, six inches apart, which I have only renewed about twice in ten years; the fruit is always excellent, and supplies a large family all the strawberry season, which saves much garden ground for that crop. The space betwixt the borders, I cultivated at my leisure; some were appropriated for nursery ground, some for potatoes, peas, cabbages, &c.; some for experimental agriculture, lucerne, mangold wurzel, &c. The orchard has succeeded beyond my utmost expectations. I had forty-eight apples from two Keswick Codlins the first year, but have never had patience to count them since: last year I had at least seven bushels off the same two trees! Six dwarf Hawthornens produced above fifteen bushels, and I have, at this moment, two bushels of Wyker pippins from one graft of my own putting in, only ten years ago. Two Dumelow's seedlings, planted twelve years ago, produced at least eight bushels of beautiful fruit, scarcely one of them less than ten inches round, and many of them twelve. The Nonpareils are a very similar crop; as for the Mank's apple, &c. there are generally as many apples as leaves; and when in blossom they seem an entire bunch of flowers.

(From the Genesec Farmer.)

CURCULIO, LIVE HEDGES, &c.

Greatfield, 2 mo. 18, 1833.

D. LONGSTRETH says that a gage plum tree which stood over a pavement, ripened its fruit in perfection the last season, while all the fruit of his other trees of that kind, which were not over pavements, was destroyed by the curculio. In order to show that this result was caused by the pavement he says that a plum tree, standing near the path to the barn, not paved but which was frequented almost hourly, lost all its fruit. Such facts ought to be recorded and generally known.

His account of the thorn hedges near Philadelphia, is discouraging. The destruction of the English

thorn, many years ago on Long Island, had deterred some cultivators from employing *exotics* for hedges; but no danger was apprehended of the decline of American species. It is found however, that many hedges of the Washington or Potomac thorn (*Crataegus cordata*) have latterly become so much infested and damaged by insects, that little hope is entertained of their recovery. A farmer of Abington in Montgomery county, Pa. has expended more than \$100 in the purchase of these thorns; and he now considers his money and labor both lost.

According to Dr. MEASE, the New Castle thorn is another species (*Crataegus crus galli*). The late Judge PETERS says, "In the summer of 1812 I visited the garden and shrubberies of Mr. McMahon. Most of his thorn plants were leafless. The New Castle thorn was an exception. I never beheld a more verdant, vigorous plant. The contrast with other thorns was striking and captivating. He, with reason, prefers it on every account. It has every valuable attribute of other thorns. It superadds the capacity of resisting the maladies, and thriving amid the misfortunes to which others are subject."

Will any correspondent oblige me by continuing his examinations so far as to determine whether the New Castle thorn is still exempt from the maladies to which others are subject. D. T.

RURAL ECONOMY.

(From the New York Farmer.)

COTSWOLD AND OTHER VARIETIES OF SHEEP.

MR. LEBER.

In your last number are some queries, by a subscriber, respecting Cotswold sheep, which would be answered differently by different persons; but let each person who knows them contribute his mite. There are in various parts of England high rolling lands called wolds, as in Yorkshire, Lincolnshire, Gloucestershire. The last are called the Cotswold hills, from an old practice of cutting or housing sheep, but this practice is now out of date. Cotswold sheep are long-wooled, large, and strong built, have white faces and legs, broad noses, and are without horns. They have some Leicester blood in them, from which all the long-wooled breeds in England have received great benefit. They are, however, a coarser and heavier kind of sheep than the Leicester.

A few years ago, being amongst the farmers there, I found that large lots of Cotswold wethers, four tons or thereabouts, might be had which would weigh on an average fifty-six pounds per quarter. I there saw them in the butchers' shops, at Gloucester, of full that weight, and close to them were hanging carcasses of the beautiful little Ryeland sheep, weighing only fourteen or sixteen pounds per quarter, but worth more per pound. In the market were tups for sale, large good sheep; their length struck the eye directly. A Mr. Large, of Bodwell, Oxfordshire, on the border of Gloucestershire, gained many prizes at the Southfield show, for his Cotswold sheep; one of which weighed sixty-two and a half pounds per quarter, or two hundred and fifty pounds the carcass. But now that we no longer find so heavy, two sheep to make the weight are found much better in all respects, and I have seen them lately, at the London Christmas shows, weighing from thirty to thirty-six pounds per quarter.

The remarks of Mr. Smith are slightly incorrect. The land on the Cotswolds is not poor, for if it were so, heavy long-wooled sheep could not live much less get fat on it. The climate is not cold, being in the south of England, but wet and bleak. These sheep never live hard, and in winter you may see thousands of them feeding off turnips on the land, with a stack of hay in the middle of the field, and no shelter but

stone fences, not a tree nor a hedge. They are hardy, good-constituted sheep, but require abundance of moist as well as dry food in winter, or they would rapidly degenerate in wool and carcass.

In the small territory of Great Britain are various breeds of cattle and sheep, adapted to the soils on which they are kept, and nothing strikes an Englishman more than the little variety seen here. The common sheep of the United States are evidently from the same stock as the heath sheep of England, such as may be seen on Bagshot heath, the Derbyshire hills, and other places. These common sheep have in most districts been crossed with merinos, the wool of which ought to be excellent indeed to make up for their ill-formed carcasses. Of late years many Leicesters have been brought from England, and an excellent breed they are, but coming from a mild, moist climate, and rich soil, some of them and their descendants have suffered severely when wintered in the way that is too common here. Some Lincolns and Southdowns have been brought, but there are other good sheep which have never been introduced. The large Dorsets, which, with a kindred breed of Somerset sheep, supply the London market with house lamb, are well worth being imported and tried in some parts of the middle states. The Ryelands are good sheep, but would not suit the many who look to size instead of symmetry. Would it not be worth while for some of the agricultural societies to introduce these, with some of the smaller varieties of British cattle as yet unknown here?

The number of sheep kept in England and Scotland is immense, and at the large sheep fairs, at stated times, in every part of the country, a stranger may see every variety. At Wey, in Hampshire, I have seen one hundred and twenty thousand sheep penned for sale. These were chiefly Hampshire Downs of all ages, assorted in lots, so that a buyer could find ewe lambs in one pen, wether lambs in another, then shearlings, or two-tooths as they call them, &c. Besides these, but not penned, were many flocks of Dorset and Somerset ewes, some of which then, (10th October,) were within a few days of lambing. In England, beef and mutton are nearly the same price, and the latter is a favorite meat. Here it certainly is not so, for though the beef and pork are good, mutton is not so, and the inferior quality accounts for the price. H.

P. S. The price of Cotswold mutton, in England, is like that of all the large long-wooled sheep, less than that of smaller sheep; but even these of late years have been bred there with so much pains, that they fatten earlier than formerly, and, not having age, their mutton has not so much flavor as it used to have. Some gentlemen keep wethers to a good age for their own tables; but the farmer, of course, makes the most profit he can, and sells fat, at two years old, sheep which formerly would have been kept to twice the age.

(From the Genesee Farmer.)

DISEASES OF ANIMALS.

ON THE CAUSE AND PREVENTION OF FOOT-ROT IN SHEEP.

I find an excellent and somewhat lengthy paper upon this subject in the second volume of the *Quarterly Journal of Agriculture*, by Mr. Dick, veterinary surgeon, Edinburgh, of which I have made a brief abstract.

Mr. Dick first describes the structure and functions of the foot, and their adaptation to the habits of the animal, in a state of nature. The sheep is naturally an alpine animal, dwelling, by preference, among the steepest and most inaccessible summits of lofty mountains. Amid these ranges, the hoofs are worn away as they grow, and are consequently always fresh and sound.

"But what, he asks, is the effect of domestication? What do we gain by enticing the sheep from

his native and natural haunts, to the richer pastures of our meadows or our lawns? There the animal enjoys a more luxuriant pasturage; it fattens to a larger size, and will, in this respect, repay the increased allowance which has been made to it. But instead of moving about in small troops, with the alacrity of the wild kinds, the sheep are seen in flocks of thousands moving slowly over their pastures, and gorging themselves to an extent which cuts short the thread of life, by the advancement of various diseases. Instead of wandering from the summit of one peak to another, in quest of a scanty subsistence; or, instead of being compelled to descend from the summits of the mountains in the morning, and ascend again in the evening, they are compelled, in many cases, to remain within a few yards of a particular spot, for weeks together, and there engorge themselves to satiety.

For want of the friction upon hard surfaces the hoof becomes overgrown. "The crest, the part naturally intended to support the weight of the animal, is allowed to grow out of all due bounds, because the softness of the pasturage upon which it now moves, presents little, if any, of that rough friction to which the feet of the animal is naturally intended to be exposed. The crust, therefore, grows unrestrained, until it either lays over the sole, like the loose sole of an old shoe, and seems to retain and accumulate earth and filth, or is broken off in detached parts, in some cases exposing the quick, or opening new pores, into which particles of earth or sand force their way, until reaching the quick, an inflammation is set up, which, in its progress, alters or destroys the whole foot," the system becomes diseased, and the animal dies.

Mr. Dick explodes the idea that the disease is contagious. He thinks it promoted by soft old pastures, luxuriant herbage, and particularly by wet seasons, and wet grounds. To cure the disease, Mr. Dick recommends that the detached hoof be pared away, and some caustic applied to the surface, of which muriate of antimony is the best. To prevent the disease, he recommends that the hoofs be rasped or paired at regular intervals; that the sheep be made to travel upon hard surfaces, or folded in a place purposely prepared, upon which they would move about every day, and wear their hoofs.

The whole of this paper is worthy of the careful perusal of the sheep farmer, and will be found from page 852 to 865 in the work I have quoted. Mr. Dick's paper sufficiently indicates, what other considerations concur in establishing.

1. That sheep are far more healthy when suffered to range upon the sides of precipitous hills and mountains, where they obtain short feed, pure and dry air, stony bottom and plenty of exercise. And

2. That consequently our hilly districts must ultimately be resorted to for the profitable and successful rearing of this valuable animal. B.

(From the New England Farmer.)

DISEASE IN CATTLE.

We have published several communications relative to a disease in cattle sometimes called a *hold fast*, a tumor on the jaw which is believed to be incurable. It did not then occur to us that we had before been favored with an account of a similar, or, probably, same disorder, which we published in the *New England Farmer*, vol. iii. p. 211. As this gives a statement of the common cause of this evil, and other circumstances connected with it, a republication of the substance of the notices referred to may be serviceable to some cultivators, not in possession of the volume which contains them.

E. Hersey Derby, Esq. in a communication dated February 15th, 1825, observes as follows:

Some time in last May I observed a swelling on the side of the face of a valuable ox, and requested several persons to examine it. They called it a hold-fast. I afterwards requested a surgeon to look at it, and

* This thorn is also a native of Cayuga county, N. Y.

advise me what mode to adopt for the relief of the animal. He thought a cure could not be effected except by laying open the part and extracting the tumor, which I considered too hazardous an experiment. A farrier, in this vicinity, supposed it might proceed from some defective teeth;—I allowed him to extract three, directly under the swelling, and to insert a rowel in it: in a few days it discharged copiously, and the animal seemed much relieved;—I flattered myself he would effect a perfect cure.

Some time after the rowel was taken out, the swelling increased very rapidly, and in December I found it necessary to slaughter the animal. I sent the head to Dr. Peabody, desiring him to give me some account of the case. I enclose you his answer.

The following is extracted from Dr. Peabody's observations on the case, in answer to Mr. Derby's request.

There is in each cheek bone of the ox a large irregular cavity, above the range of the teeth, sufficiently capacious to contain half a pint. The external portion of bone, covering this cavity, is about two lines, or two-tenths of an inch in thickness. The internal bones are also thin. This cavity in a healthy state is empty.

The fleshy tumor was over this cavity, which I in the first place, dissected off, and which was as large as a man's two hands placed together. This tumor appeared to have commenced upon the exterior bone of the cavity, and was very firmly and intimately connected with it. It consisted of what we call *schirrous* or indurated flesh, and near the same bone was, perhaps, a gill of pus. The bone itself was considerably absorbed, that is it had lost its consistence as bone, so that I could push my dissecting knife through it. The cavity (which in health was empty,) was filled with a diseased substance, most of which was as hard as *schirrous*, the remaining part was coagulated lymph. If the ox had not been killed, the matter, or pus above mentioned, must have found its way out, and in this instance through the gum, outside of the teeth. And the disease, being so extensive, must have been incurable.

The cause of this disease, I have no doubt, originated in external violence. I believe I suggested this idea to you when I saw the ox alive at your farm. I have conversed with a very intelligent medical gentleman since, who has lived in the country and who has been acquainted with a number of cases, some of which have been traced to external violence. This violence is inflicted by cruel teamsters. The bone, as stated is thin, and a heavy blow with the butt end of a heavy whipstaff is sufficient to fracture it. An accident of this kind will be followed by swelling and infusion into the cavity, which will destroy the texture of the bone, and eventually become an open sore, and be incurable. There are different degrees of the disease according to the degree of violence. In some cases the violence may not fracture the bone; in such cases there may be a temporary swelling, which will subside. Or if the fracture be slight, there may be a spontaneous cure from the efforts of nature. In such cases the appearance of disease will subside in a few weeks, but when the swelling continues or increases, after four or five weeks, I should think the disease may be considered as incurable, and the sooner the animal is killed the better.

Now one word on the cruelty inflicted on these dumb animals. I have seen oxen pounded not only with the butt end of a heavy whip-staff, applied with all the strength of a frantic athletic man, or more properly, *brute*—but I have seen them struck over the face with the handle of a hay-fork nearly two inches in diameter, or with a *handspike*. Such blows produce this disease, and as a proof of it, it never occurs in any other part of the animal. Now would it not be well that a law should be enacted and enforced, regulating the size of whip-staves, and that a teamster using or carrying a whip-staff over a certain size, which should

always be made so small as not to injure the bones of an animal, should be subject to a heavy penalty? It is shocking to humanity to witness the brutal cruelty inflicted upon the noble horse and useful ox, and it calls loudly for some effectual remedy.

BROKEN WIND.—A broken winded horse had been kept in a field where there was not any water except in the bottom of an old blue kiln, and had recovered his wind. The owner ordered a stable shovel full of quick lime to be renewed every five or six days, and the water to be poured off, and a bucket of it given every day to a broken winded coach horse aged eight years, which had almost a constant cough. The horse was supplied with water thus prepared for about five weeks, and kept in the stable. He is now perfectly recovered in his wind, and free from a cough.—*Farmers' Reporter.*

He that hath a trade hath an estate; and he that hath a calling hath a place of profit and honor. A ploughman on his legs is higher than a gentleman on his knees.—*Dr. Franklin.*

MISCELLANEOUS.

(From the Genesee Farmer.)

LIBRARY OF ENTERTAINING KNOWLEDGE—RICE BUNTING.

Greatfield, 1st mo. 19, 1833.

The Library of Entertaining Knowledge is published under the superintendence of the same society as the Library of Useful Knowledge. It is understood that this association includes many of the most eminent men in Great Britain who favor a more general diffusion of knowledge; and Lord Chancellor Brougham is, or has been, chairman of the committee. It is therefore, as we have a right to expect, a work of great merit; and in many instances the researches of naturalists, which have been heretofore confined in volumes beyond the reach of common readers, are lucidly arranged and presented in a popular form, illustrated by numerous figures or engravings. A *number* (bound like many of the French books in paper) contains about 216 pages; and *two numbers* form a neat duodecimo volume. I have just received the 30th *number*, which appears to have been written in the early part of last year, (1832.)

There is internal evidence that much labor has been applied in the preparation of the different articles; but sometimes, through haste or inadvertence, errors have escaped undetected by the publishing committee. Such defects appear indeed to be rare, but they rise in importance with the high character of this work which insures them a widely extended circulation; and it may be some slight assistance to the cause in which that society is engaged, to point out some of those errors, from time to time, in the Genesee Farmer.

THE RICE BUNTING.

Under the head of *RICE* we are presented with the following account of a bird with which we are all familiar, known to some persons by the name of *Rice bunting*, and *Reed bird* from its food, and to others by the name of *Conquella* from its notes.

"The cultivators of Rice in America sometimes suffer severely from the depredations of the *Rice bird* of Catesby, (*Emberiza oryzivora*.) known familiarly in the country by the name of Bob Lincoln. This bird is about six or seven inches long; its head and the under part of its body are black, the upper part is a mixture of black, white, and yellow, and the legs are red. Immense flocks of these birds are seen in the island of Cuba, where the rice crop precedes that of Carolina, but when from the hardening of the grain the rice in that quarter is no longer agreeable to them, they migrate towards the north, and pass over the

sea in such numerous parties as to be sometimes heard in their flight by sailors frequenting that course. These birds appear in Carolina while the rice is yet milky. Their attacks upon the grain while in this state, are so destructive as to bring considerable loss upon the farmers. The birds arrive in the United States very lean, but thrive so well upon their favorite diet, that during the three weeks to which their visit is usually limited, they become excessively fat, so as to fly with difficulty, and when shot to be burst with the fall. So soon as the rice begins to harden here, they retire to other parts, remaining in one place only so long as the rice continues green. When this food entirely fails they have recourse for their subsistence to insects until the maize begins to form its grains, and then the milky substance which these contain is devoured with the same avidity that marks their attacks upon the rice plant."

The brief history of this bird is as follows: It leaves the intertropical regions early in spring; and directing its course slowly through the southern parts of the United States, passes on in great numbers to breed north of the fortieth degree of latitude. At this time the sexes are very distinguishable by their colors. Early in summer however, the color of the male begins to change, gradually assimilating to those of the female; and towards its close, the parents with their broods, joining in large flocks, on their way southward, attack in succession the late sown oat fields of New York and New England, the wild rice along the shores of the Delaware, and the cultivated rice of South Carolina and Georgia. It then passes into Cuba and soon after into Jamaica. See WILSON, AUDUBON, and NUTTALL.

The notion of their passing in autumn from Cuba into Carolina to eat rice was a misconception of CATESBY. Lying in a bay at Andros' Island one night in "September" he heard three successive flocks of birds passing over to the northward; and concluded from their notes that these were ricebirds. He adds: "I conceive after partaking of the earlier crop of rice at Cuba, they travel over sea to Carolina for the same intent, the rice there being at that time fit for them." We have seen however, that the *rice birds* at that very time were journeying southward from the northern parts of the United States; that their favorite kinds of food, with which our country abounds, were already spread before them; and they could have had no inducement to go to Cuba, for the rice harvest in the southern states, "commences at the end of August."

Their *leanness* at this season; and their *subsisting on insects* after the rice is gone and while they are waiting for the maize to form its grains, are equally fictitious; for though the time of planting Indian corn is more extended in the southern states than in higher latitudes, owing to a greater length of the warm season, yet a portion is in the milky state quite soon enough to save Bob Lincoln from any such necessity.

I omit some minor objections, but observe that *the back* of its head is *not black*, though so represented in NUTTALL'S figure. WILSON says, "back of the head a cream color;" AUDUBON, "back of the head and neck, brownish yellow." NUTTALL: "the hind head, yellowish white." It is from this circumstance that it takes one of its local names, the *skunk black bird*.

I would now remark that this paragraph from the Library of Entertaining Knowledge, though very erroneous, affords proof of the research of the author, who only failed by not making a better selection of books. So much has been done for American ornithology in the last twenty-five years, that he who exclusively consults older authors, places himself far in the back ground. D. T.

ITALIAN SILK REEL FOR SALE.

An Italian Silk Reel, imported from Genoa, for sale. Inquire at the American Farmer Establishment. Letters post paid. Price \$10. This will not be repeated.

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale.

Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life), is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also, — A young JACK, a son of Don Carlos, 4 years old, 43 inches high, well made, stout and promising, of same color as his sire — price \$150.

Also, — A full sister of the last, 3 years old, 41 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

PUBLIC SALE OF DURHAM SHORTHORNED CATTLE AND HIGHLY IMPROVED SHEEP

Will be sold on Wednesday, 29th day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd, the highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEIFERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young Lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand.

DAVID MEADE, Administrator.

April 5, — St

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals, — viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	300
Do 2 " " Do "	250
Do 1½ " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each.

Half Blood and upwards. — A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenths Durham Shorthorn, very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$100.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address L. I. HITCHCOCK,
Amer. Far. Office.

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at \$1 per bushel.

L. I. HITCHCOCK,
American Farmer Office and Seed Store.

200,000 WHITE MULBERRY TREES.

The Sub-scriber has on hand and for sale 200,000 White Mulberry Trees of two and three years' growth, which have been transplanted, are in a healthy and thrifty condition, and which he offers for sale at \$1.50 and \$2.00 per hundred, delivered at the nursery.

Also, a few of the *Morus Multicaulis*, or Chinese White Mulberry.

ASA BUTLER,
Suffield, Connecticut.

P. S. All orders (post paid) will be punctually attended to. April 12, — 6t.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

SINCLAIR AND MOORES NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices; — after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Bushes, (among which is the much admired Greville.) double Altheas, Honeysuckles, Corcorus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Ailanthus, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Neetarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets. Feb. 22.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET. — There is a decline to a trifling extent in the flour market. Sales of Howard street flour have been made within the range of our quotation. From some unknown cause some of our city mills flour has attained the ascendancy over Howard street in South America, and therefore a few sales have been made of it for that market at a considerable advance upon the price of Howard street.

TOBACCO. — Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00. — Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00. — Fine yellow, 18.00 a 25.00. — Virginia, 4.00 a —. — Rappahannock, 3.00 a 4.00. — Kentucky, 3.50 a 8.00. The inspections of the week comprise 726 hhds. Md.; 124 hhds. Ohio; 2 hhds. Ken. and 1 hds. Vir. — total 853 hhds.

BALTIMORE, FRIDAY, MAY 3, 1833.

HORIZONTAL PLOUGHING—HILLSIDE PLOUGHS.

MR. SMITH: *Virginia, April 17.*
Not long since, in a party of friends, discoursing on the subject of agriculture;—its past history and present state in Virginia, the topics of *horizontal ploughing* and *hillside ploughs* came up; and a question was raised as to the real author or authors of these improvements. To the late Gov. Randolph, of this state, their *original invention* has by many been ascribed. If so, he merited the thanks of the whole agricultural community; and perhaps not the less if he merely *introduced* them both; and improved the construction of the latter, (the principle having been before suggested,) a degree of credit which is perhaps all that was ever claimed, either by himself or by his friends for him. As there however seems to be some doubt in the minds of some, on these points, I have thought proper to appeal to yourself, as being a probable source of the most correct information on this subject.

I hope you will excuse the following queries, as they proceed from a desire to ascertain the truth of history, (and why should not the history of agriculture be interesting to farmers?) or perhaps from the less dignified, though equally innocent disposition of an antiquary:

1st. Was "horizontal ploughing" first practised by Gov. Randolph, as some have supposed?

2d. Was he the original inventor of the "hillside" plough.

3d. Even supposing the ideas in either or both cases to have been original with him; were they *new*?

To these, I am much tempted to add a fourth—i. e. whether in many parts of our country, ploughing *truly* and *exactly* horizontal, would be a blessing or a curse?

That this question is not entirely without meaning, may hereafter appear.

Answers to these would be duly appreciated, by

A VIRGINIAN.

Probably "A Virginian" is in possession of all the facts extant on the subject of his communication. That Gov. Randolph first practised horizontal ploughing in this country, there can be little doubt; but that he was the original inventor of the mode, or of the hillside plough, is a matter of dispute. Certain it is, that horizontal ploughing was recommended by Columella, and most probably practised by the Romans; and of course a hillside plough of some sort was used by them. But that Gov. Randolph *introduced* both the mode of ploughing and the plough, and thus conferred a most important benefit upon his country, and particularly upon "Old Albemarle," there can be no question; nor can there be any as to the degree of honor due to him for the service thus rendered his country. It may be said that he merely happened to be the first to practice upon an old theory, and thus brought it into notice; but this is not correct. The theory was at least eighteen hundred years old, and had been passed by as unworthy of attention during the whole of that time; or at least it was resorted to merely by writers, for we have no record of its being reduced to practice. Now, although the genius of invention was not necessary to bring it into successful operation, there certainly was a genius and a spirit required to meet and overcome the prejudices and habits of routine of the people, more creditable to the possessor than a mere inventive genius could be.

Answers to the queries of our correspondent may be gathered from these remarks, so far as we feel authorized to speak. We regard Gov. Randolph, as the true author of horizontal ploughing, and of the hillside plough, because he has blessed our country with them, and we care not where he obtained the idea.

To the fourth question, we can only say that if there is a hill on the face of the earth that would not be benefited by horizontal ploughing in preference to the common mode, we are unacquainted with it;—of course we know of no part of our country where exact horizontal ploughing would be a curse, or would not be a blessing.

CATERPILLARS.

MR. SMITH: *April 26, 1833.*
I never have seen caterpillars so abundant in my life. My apple and peach trees were full of them. We commenced shooting powder at them, but found this would be a never ending means of destroying them. I set three men at work with mops of cloth fixed on the points of long poles, and by dousing them with a strong solution of salt and water, we have destroyed them nearly all. Yours, truly, T. P.

THE HORTICULTURAL SOCIETY OF MARYLAND.

For the diffusion of Horticultural Science and the Improvement of the Art of Gardening; Associated Nov. 20th—Incorporated by act of the legislature, at December session, 1832.

The Council of this Association have resolved to open the public proceedings of the society, by an exhibition of plants, flowers, fruits and other vegetable productions.

The exhibition will be opened on the eleventh day of June next, and will continue during that and the following day.

On the eleventh of June, popular lectures will be given in the hall of exhibition, and on the twelfth the society will hold a public meeting, when an address will be delivered.

In furtherance of the views of the society, the Council have resolved to offer premiums to the aggregate amount of one hundred dollars, to be awarded to the finest objects exhibited, by a committee of judges appointed for that purpose.

The following gentlemen have been appointed to act as committee of arrangement, viz: H. F. Dickhut, chairman, Z. Waters, Geo. Fitzhugh, James Moore, Edward Kritz, I. I. Hitchcock, Sam. Feast, John Feast.

All who feel interested in the advancement of Horticulture, are invited to lend their aid in furtherance of this design. Those wishing to exhibit plants or other objects of Horticultural interest, will please communicate their views to the committee of arrangement, stating at the same time the articles they design to exhibit.

Letters on the subject, must be addressed to the chairman of the committee, from whom any further information may be obtained.

May 3.

BUILDING HOUSES.

We extract from an able article in Silliman's Journal, on *Domestic Architecture*, the following on the subject of building houses, which we think will attract the interest and attention of many of our readers.

Smaller cities and towns have a great advantage in the intervals which occur between the houses, and in New England this advantage is turned to good account. The houses there are frequently built at a distance of twenty or thirty feet from each other, a space of several yards being also left between them and the streets.—The whole of this is planted with delicate shade trees and shrubs, and as the houses themselves are usually painted white and have small tasteful porticos in front, the effect is the most agreeable that can be imagined. Gentlemen who have travelled extensively in Europe, frequently inform us that they have never seen any thing that, as a whole, would compare in neatness and real beauty with some of the New England villages. It is a beauty in the power of every one of our towns, for the houses in

New England, though as comfortable and durable as in other places, cost I believe even less than is usual for edifices of their size. Nearly the whole is effected by the neat little yard, with its verdure, in contrast with the pure white of the facade, and by the little portico over the door. There is another characteristic in these towns, which I should like to see more common in the country; I mean the habit of planting trees along the streets. We should not have all the streets in a town treated in this manner; those for business should be kept clear, but in all others trees should be planted more or less thickly, as taste or convenience will admit. They give a town the appearance of richness and comfort, which cannot be so cheaply procured in any other manner. The elm is our most graceful shade tree, and will be found most suitable when the streets are wide; when narrow, the maple, I believe, is found to answer best.

As to country houses and their premises, so much depends on the character of the ground, and of all objects, even to a distance of miles, that the subject swells entirely beyond our limits. I must be allowed, however, to remonstrate against the warfare which is every where carried on against our noble forest trees, trees which should be estimated by us as far above all price. The first thing done in the new parts of our country, when a spot is determined on for a house, is to cut down all the trees within many rods of it, and then year by year, the work of destruction goes on, as if the very sight of a forest tree were odious. The house stands alone in the clearing, its inmates, and particularly the children roasted and browned under the hot summer's sun; but by and by, the nakedness of the situation is felt, and then are planted some Lombardy poplars "all in a row." Now, the trees which we cut down with such an unsparing hand, are the very kind which English gardeners cultivate with the most persevering diligence; and are planted here just as they labor most to plant.—And we too shall cultivate them before long, and shall then think, with the most bitter regret, of the sad destruction which we and our ancestors have made. But in vain; for all the art of man will not be able to restore in any length of time, such glades and thickets, and lawns, as we now possess. When about to build in a new country, we should save, near our house, an acre or two of the forest, and should guard it with the most watchful care. Morning, noon, and evening, it would be an agreeable retreat; its shade would be refreshing in our scorching heats; it would connect us in some measure, with ages long since gone, and would bring before us the wild, but high souled Indian, his council, his battle song, the war, the chase, the feast and dance; its noble and manly forms would gratify our taste; it would raise our thoughts to Him who is "a shadow from the heat, a strength to the needy in his distress." I say again, let us spare our noble forest trees. Many political considerations might be adduced to show the imprudence of our rude havoc among them, but for these we have not room.

USEFUL TABLE.

The number of plants which may be planted on an acre = 160 rods or poles = 4340 yards = 43,560 feet, is as follows:

Ft. apart.	No. plants.	Ft. apart.	No. plants.
1	43,560	11	360
1½	19,360	12	302
2	10,890	13	257
2½	6,969	14	222
3	4,840	15	193
3½	3,556	16	170
4	2,722	17	150
4½	2,151	18	134
5	1,712	19	120
6	1,210	20	108
7	889	25	69
8	680	30	48
9	517	35	35
10	435	40	27

AGRICULTURE.

(From Proceedings of the N. Y. State Agricul. Society.)

ON PRACTICAL HUSBANDRY.

Schaghticoke, October 25, 1852.

SIR,—I received your circular of the 24th Feb. together with the constitution and by-laws of the New York State Agricultural Society, and a packet of mulberry seed. And I now proceed, agreeably to your request, to give you some outlines of my farming, and of my observations in practical husbandry. The improvements in labor, in the expense of tillage, and in the other operations of husbandry, I think have produced a saving in expense, in the last fifteen years, of nearly fifty per cent.

Horses constitute our principal teams for tilling the soil and transporting our produce to market. Very little improvement has been made in their breed among us for the last 25 years. To be adapted to farm labor, these animals should have straight limbs, short neck, large boned breast, thick boned legs, common sized hoofs, thick main and tail, be well filled up in the flank or short ribs, and sixteen and a half hands high. A straight back denotes toughness for service of any kind. These points are best united in what we call Dutch horses. The encouragement given to racing, and the introduction of breeds adapted to that object, seems to be the principal cause of our working horses being poorer than they were twenty-five years ago. In racehorses lightness of form, and swiftness of motion are most desirable; but farmers require in their horses strength of muscle and limb, which are not to be acquired by encouraging breeds of opposite qualities.

In tillage husbandry, great additional profit is obtained by sowing about 4 lbs. clover seed per acre with small grains, which answers on interval lands, where plaster has no effect. This answers well for a bed of manure, when ploughed under, and will bear good crops for six years in succession. My course is corn, barley, pease or flax, and sometimes oats, and when these are gathered, I plough for wheat the same season, and sow in September. After the wheat is harvested, the field is pastured till spring, when I again plough for corn, and treat as before, until the second crop of wheat comes round, when it is sown in the spring with clover. The clover is mown one year, pastured, and the ground ploughed for wheat the same season. By so doing, land will improve instead of deteriorating, and will net an annual income equal to any bank stock, and certainly much pleasanter. Elevated lands will produce a good crop three years in succession, if the soil be gravel or sand, by adding a bushel of plaster to 4 lbs. of clover seed per acre, and treated as above. Clay soil requires animal manure as often as every three years, then treated as above it will produce a good crop. Farming business thus conducted, if the season is good, will produce a crop of any kind. I have found that it is better to spread animal manure mixed with straw or hay when fresh and plough it in, so as to have the fermentation take place under ground, thus preventing the heat of the atmosphere from producing too rapid a fermentation, that its properties may be absorbed by the soil.

The principal object for which lime is to be used in the cultivation of grain, is to prevent the ravages of insects. This is done by soaking the grain to be sown in lime water, and then rolling it in plaster of paris. I have been troubled this season by the weevil upon my wheat; it appeared about the first of July, in the form of a small yellow worm, upon each kernel of wheat under the chaff. It disappeared after the first shower of rain. After the wheat was gathered we discovered great numbers of flies upon the straw, which we supposed to be the weevil in another state: they have six legs and a sharp pointed proboscis, are of a light color, afterwards becoming dark; have wings but do not seem to fly. It is now October and these flies have not disappeared. They

have come on gradually from the north, and have been found to continue about three years in a place. Is it not probable that the fly has deposited the eggs, to be seen in gathering next year's crop? It is thought that tobacco is the best thing yet discovered to destroy them.

Flax should be sowed for a good crop after potatoes, and not oftener than once in seven years upon the same ground—which I have found by experience. There have been within a few years great improvements made in the implements of husbandry. Among these the reversed horse rake, in gathering hay, barley and pease, I have used for the last two years, and find it will enable one man and horse to do more work than six men in the common way, and do the work well. I have this season purchased one of Humphrey's patent threshing machines. It is simple in its construction, and can be purchased for \$60. With one horse and two men I will engage to do the labor of eight men, and thresh it perfectly clean. It leaves the straw almost full length, and worth more for fodder than it can be made in any other way.

The mulberry seed which I received from the society, I divided between four or five friends and myself. We sowed it in drills, in different kinds of soil, about the 15th of May. The plants are all doing as well as could have been expected from the coldness of the season. They are from fifteen inches to two feet high. I have tried for several years various methods of preparing cider. I have had the last year the best I ever made. Some I bottled without any addition, and to some I added a pint of mustard seed to a barrel. The latter is as clear as wine and of a delightful flavor; keeping much better, provided it be tightly bunged. Respecting the manufacture of cloth—In the first place we will take one pound of wool at 50 cents per pound, 6 cents for carding, 27 cents for spinning, 124 cents for weaving. Thus a yard and a half of flannel would cost 95 cents. Flannel of the same quality can be bought for less at the shops. As I am situated, having all my labor to hire, I find it better to sell my wool and buy goods to supply the wants of my family than to attempt to have them manufactured. But where a farmer has a large family of daughters, it is an object to manufacture as much as possible within themselves—it will pay their board and be useful employment. The same remark will apply to flax.

Of domestic wines—1st, Elderberry wine—To a quart of berries put a pint of water, and let them stand over night. In the morning mash them and let them just boil; then to a quart of juice put a pound of sugar, an ounce of cloves and a table spoonful of ginger to three gallons of water; boil and skim till clear, and when nearly cold spread your yeast upon toast and put it in your cask; let it work as long as it will, keeping your cask always full; when done working seal and cork it tight. In preparing wine it is always necessary to burn a rag wet in sulphur in the bung hole of the cask. This ought also to be done with cider. Apples will keep better than any other way put up in oats packed and headed tight to keep them from the air. In preserving fruits it is an improvement upon the usual method to let the fruit and syrup both be cold before they are put together.

Your friend, A. KNICKERBACKER.
J. BUEL, Esq.

(From the Genesee Farmer.)

AGRICULTURAL IMPROVEMENTS IN SCOTLAND.

Agricultural improvements in Scotland have probably been greater, during the last fifty years, than in any other part of Europe. In this period of time, a large portion of that country has been converted from unproductive naked wastes, of moss and hills, into fertile arable lands, pastures and wood, through the magic influence of enterprise, industry and science. Two of the most efficient operations in producing this change have been planting and draining. Thou-

sands of acres of naked hills have been annually planted with forest trees, which have afforded the triple advantages of beauty, shelter and profit. Thousands of acres of moss or morass, have been annually drained, and reclaimed to the uses of husbandry, at an expense which would startle our farmers, and yet with a profit that invites imitation. To take the first example which presents in a work before us: The expense of draining and embanking Barr Loch and the adjoining grounds, cost £10,000. The area of the Loch comprised about two hundred and thirty acres. The increased product or value of this ground, in the two years after the drainage was completed, amounted to thirteen per cent. on the outlay.

This great improvement in the agriculture and prosperity of Scotland, has been mainly accomplished through the combined exertions of her most wealthy, most scientific and best practical men, concentrated and brought to a focus in her "*Highland Society*."—This society was formed in 1784, and now numbers about two thousand members; and embraces her nobility, her wealthy merchants and mechanics, her men of literature and science, as well as her best practical farmers. The annual contribution of each member is about five dollars. It would seem that there all appreciate the importance of this great branch of labor and source of national wealth; that all feel desirous to promote its improvements, as directly or indirectly affecting their individual interests. A Quarterly Journal records its transactions, embracing the communications and prize essays transmitted to the society. And perhaps there is not a periodical which affords more useful and practical information to the intelligent husbandman than the Edinburgh Quarterly Journal of Agriculture. The objects of the society embrace the improvement of every branch of labor connected with husbandry. I venture to send you an abstract of the premiums offered by the society in 1829. It will show the diversified objects to which the society is directing its attention, the liberal rewards which it holds out for useful undertakings and improvements, and I think cannot fail to afford useful hints to our agricultural societies in the disposal of their premiums. The following is the abstract:

IRRIGATION.

Pittsford, March 20, 1833.

The advantages of irrigating land, especially grass land, are not unknown; still it is very generally neglected. Most farmers know the benefit of turning the water from the road side upon their mowing lots, and yet they will suffer the permanent streams that run through their farms to pursue their natural courses, without ever diverting one drop into artificial channels to fertilize and enrich their fields. True, that in a country as level as western New York, much less advantage can be taken of streams, than in a country abounding in hills. Yet there are hundreds of farms in Monroe county, that might be greatly improved by judiciously diverting the streams from their accustomed courses, and hundreds of tons of hay might be added, with very little expense to the annual crop.

In the hilly country of Vermont, I owned a farm, over which I carried the water of a small stream in artificial channels, more than a mile. Lands that did not yield half a ton to an acre, were thus made at once to yield two tons; by which means I added to my crop six or eight tons. A little experience taught me that I could carry water where I had not the least suspicion it could be carried. Every stream that runs with any rapidity, may be used for this purpose.

For the benefit of farmers, I will state my method of procedure. I first selected the place at which I thought best to take the water from the stream.—Here I made a dam sufficiently high to conduct the water into a channel on the bank. The dam may be made of wood or stone, as is most convenient, but stone are best, as they are most durable, and less liable to be washed away. I then drew two furrows with a plough, turning the sod down toward the stream, and pulling the sods of the second furrow upon the top of the first. This will make a channel sufficiently large for ordinary purposes, where you do not wish to carry the stream to any great distance.

These channels should be drawn as nearly level as they can be, and give a current to the water. Most

farmers draw them merely by judgment, and of course very inaccurately. I had an instrument to which was attached a spirit level, so that I could lay them with great accuracy.

But any farmer can make an instrument in fifteen minutes, that will answer the purpose very well.—Take a piece of plank five or six inches square, through this bore a hole to receive a staff about three feet long, sharpened at the lower end, to stick into the ground. This is used as a standard, on which you must lay a smooth planed board about a foot square. The method of using it is this: Place your standard below your intended canal, so that the top will be level with your dam, or the place where you design to take the water from the stream. Then turn water upon the top of your board, and so adjust it as to bring it to a level, or a little descending in the direction that you wish to draw your channel. Then with your eye look across the top of your board, and see where it strikes the ground. Here place a boy with a hoe to make a mark in the sod; and let him go on and make these marks as you direct, once in a rod, and oftener if the ground be very uneven.—Thus go through the whole extent that you wish to make your channel.

Then with your plough draw your furrows through these marks, being very careful not to fall below them, or go above them. A little care in drawing the furrows will save much labor in making the channels.—If not drawn with accuracy, it will be necessary to sink the channels in some places, and to raise the banks in others.

From these channels the water will percolate, and fill the ground below them; and you may, in as many places as you see fit, let it overflow the bank and spread on the surface. A better way is to set boards in the bank, with an auger hole for the water to flow through it in such quantity as you may wish.

Even small streams, that fail early in the summer, may be of great use, because if the ground be well saturated with water in the spring, it will give the grass a start, and if it be well watered on the first of June, it will not suffer from drought before the crop is matured.

On the subject of irrigation, I have learned much by experience, and am so confident that thousands of dollars might be added to the annual produce of our fields, that I feel desirous to see this improvement in husbandry more generally introduced. Any thing that I can do to aid my fellow citizens in such improvement, would give me pleasure.

E. D. ANDREWS.

(From Proceedings of the N. Y. State Agricul. Society.)

EXTRACTS FROM A LETTER FROM LE RAY DE CHAUMONT.

DRYING FODDER.—I have noticed a curious method of drying fodder by fermentation. I think it worth giving you some details about. They put the hay in haycocks on even ground, very soon after it is cut, i.e. 12 or 15 hours, in piling it very equally and treading it down. Rain does not injure it materially. The diameter of a haycock does not exceed four feet, and the height equal to two-thirds of this diameter. As soon as the heat produced by fermentation is too great for the hand to remain in the middle of the haycock, say 20 or 24 hours after, they use all diligence to spread the hay, bad or good weather, for it is spoiled in a few hours. Three or four hours are sufficient to dry the hay entirely. The outer part which is not fermented is put aside and treated by the ordinary means. This hay can be preserved several years without experiencing any deterioration. It has a vinous smell which cattle like when once accustomed to it. It is very well adapted to the use of cattle in general, and particularly to horses. They can eat of it freely without inconvenience, even when it is recently made. This method is chiefly advantageous

to clover and lucerne; because it dries them sooner—it prevents the leaves from falling, and preserves the nutritive principle.

CULTURE OF HEMP.—Wherever I have travelled I have observed that they cultivate hemp. I was struck with the immense expense that cultivation cost, chiefly in manure. If now and then I met with some privileged piece of ground, which by its fertility did not require such a quantity of manure, the price of the soil was so high that the mere interest of the same would have purchased, to my knowledge, in either Jefferson or Lewis counties, a similar quantity of land, as good at least for the production of hemp, and where the cultivation of it will not cost so much. I hope our society will think it advisable to recommend to the farmers a particular attention to the raising of hemp, wherever the soil is favorable to its cultivation.

(From Proceedings of the N. Y. State Agricul. Society.)

VARIETIES OF THE POTATO.

House of Representatives, U. S. February 16, 1833.

DEAR SIR:

I enclose you extracts making almost an entire copy of Mr. Lawson's essay on the potato, including his list of the varieties cultivated in Scotland, and their qualities.

I believe the publication of this essay of Mr. Lawson would be useful. But I am most anxious to obtain a like examination of the varieties of this useful plant cultivated in our state, in order that our farmers may know which are the best and worst of these varieties. With this knowledge the farmers will go on cultivating their usual and customary variety whether indifferent or bad; with correct information as to the best and most valuable varieties, it is to be hoped that the farmers will abandon the cultivation of varieties, bad or indifferent—and devote themselves to the cultivation and improvement of the best varieties. Such will certainly be the course of all wise and prudent agriculturists; and it is reasonable to expect their example will soon be followed by all others, as well from considerations of interest, as from a desire to avoid the ridicule and reproach of persevering in error and folly. With great respect,

Yours, &c.

MICHAEL HOFFMAN.

JESSE BUEL, Esq.

(From the Quarterly Journal of Agriculture, &c. &c. of the Highland Society of Scotland, No. 19, December, 1832, p. 364.)

ON THE PRINCIPAL VARIETIES OF THE POTATO, cultivated in this country. By MR. CHARLES LAWSON, Seedsman to the Society.

After some general observations on the potato, in which he expresses a doubt of the correctness of the opinion that the new varieties become bad by the age of about 14 years, Mr. Lawson says:

"No doubt extensive experience has proved, that the cultivation of any particular variety of potato, for a continued succession of crops, in the same soil and situation, injures the quality, and diminishes the quantity of the produce. But this is a law applicable to all cultivated plants, and only shows that attention to the change of circumstances and to rotation, is also necessary in the cultivation of the potato."

I proceed with further extracts:

"What is wanted regarding the potato is,—

"1. The fixed application of a particular name to each of the more important varieties;

"2. The determination of those varieties, the cultivation of which ought to be abandoned;

* Note by the transcriber. Manure well to waste money; and at the same time in your garden always plant your potatoes on the same spot, and you will probably succeed in diminishing the quantity of the crop, and be about certain to change a good into a very bad quality of potato. Such is the common practice, and such is general the result.

"3. The indication of those more particularly adapted to particular soils, situations and purposes;

"4. The knowledge of those to which we might look with most certainty as improvable by crossing.

"With these views I have prepared the following descriptive table of the varieties which I had the opportunity of growing and examining this season.

"There can be no doubt that a change of soil, climate and treatment, may alter the qualities of the tubers in a considerable degree; but it appears to me not less true, that no circumstances will very materially change the general tendency to being early or late, the general form, the color, or the general habit of growth.

"I have therefore noted these particulars as affording collectively discriminative characters of sufficient value.

"The tubers are composed of water, starch, fibrous matter, mucilage and saline extract. It is probable that the mealiness depends, either upon a due proportion of these principles, or upon the mucilage of some being more or less coagulable by heat than that of others; or it may occasionally be affected by the acidity* of the spring water, in which they are boiled. However this may be, I have noted the qualities of the different varieties as to their being mealy or waxy.

"The comparative liability to disease is the next circumstance attended to. The mode of growth of the stems whether inclined to be erect or drooping, has also been noted.

"The flavor, I apprehend, depends very materially on the increased action of the vital functions of the leaves, and does not admit of being very intelligibly expressed.

"The degree of productiveness is a matter of great importance, but can be expressed only by very general and rather vague terms.

"Although the same variety of potato, cultivated under different circumstances, may yield different proportions of its component parts, yet, as a comparative view of that ingredient of most importance in its application as food, namely, the starch, from the different varieties cultivated under the same circumstances, will afford a good criterion as to their relative value. I have ascertained this by rasping eight ounces of tuber of each variety, which being immediately mixed with a sufficient quantity of water, was poured on a fine hair sieve, through which the water passed, carrying with it the white precipitate. The weight of this sediment, deposited from the filtrated fluid, after being thoroughly dried, is marked in the table. In those cases where the difference was great, to prevent the possibility of mistake, I made second trials. I think it likely, that had the macerated potato lain for a day, and been frequently stirred, the quantity of starch would have been greater; but as the whole were done exactly in the same way, the products answer equally well, as affording a comparative view.

"In the specimens of starch produced by the different varieties, a considerable difference was perceptible, both as to color and texture; and on trying the specific gravity of twenty specimens, I found it to vary from 1 to 8 per cent.

"The fibres of eight ounces of tuber, when dried, weighed from 180 to 216 grains troy.

* Note by the transcriber. Roasted potatoes of the same variety are in general more mealy than boiled ones; and yet if the roasting be continued, it destroys the mealy quality as well as the flavor of the potato. Potatoes boiled in the waters impregnated with lime, as they are on the Mohawk, and most of the western counties, are mealy and good.

† Note by the transcriber. The very young potato is watery, and mostly destitute of flavor, and I believe nearly so of starch. Such is the quality of the tuber, while the stalks and leaves are in the most growing condition. After the leaves and flowers are perfected, and when they may be supposed most able to perform all their functions, the tuber improves—and continues to do so, until the leaves die of age.

"The specific gravity of the tubers themselves, is nearly in the same ratio as that of the starch, as above indicated. A cubic inch of twenty of the varieties which I tried, weighed from 295 to 312 grains. The comparison, however, requires to be made with greater accuracy than I can accomplish at present, in order to discover whether Mr. Knight's opinion, 'that probably the nutritive property of the potato is nearly proportionate to its specific gravity'—be correct. In the mean time, however, my friend Mr. Macgillivray has obtained for me from Doctor John Murray, the specific gravity of six of the varieties, sufficiently adapted for contrast, namely:

HORTICULTURE.

(From Proceedings of the N. Y. State Agricul. Society.)

EXTRACTS FROM A LETTER FROM LE RAY DE CHAMMONT.

Plessis, near Vendome in Touraine, 1

J. BUEL, ESQ. Dec. 16, 1832.)

Cor. Sec. of the State Agricul. Society, Albany.

Sir.—When I resolved, last summer, to pay a visit to my native country, I was much pained with the idea that it would deprive me for a considerable length of time of the satisfaction of uniting my efforts with those of such of the members of our State Agricultural Society as were zealous in promoting its success. However, I was relieved, when I considered how many there were in our society who could render the same service; while, during my travels and stay on this side of the water, I could make them useful by observations and notes collected on my route, upon whatever might be worth communicating; also, by connecting our society with some of those in France whose object is somewhat similar to ours. The alliance of such societies cannot but prove useful and produce improvements.

Having begun my travels rather late this year my information will not be as interesting as I could wish; but I hope, that during the other year I intend to appropriate to my stay in Europe, I will have collected facts more worthy the attention of our society. My travels have been through those parts of France, of the duchy of Bade and Switzerland, which have much analogy, in respect to climate, to that of New York.

CULTURE OF THE VINE—I will begin by the grape-vines.

I am still more of opinion, since I left America, that serious attention should be paid to that important cultivation. I am more certain of the success which is to attend it in the state of New York.

I have received from the county of Jefferson, information that grapes perfectly ripe have been picked from vines cultivated in open ground, and the letter which mentioned it reached me here when they had not yet begun their *rendages*, and were not expecting the grapes to be sufficiently ripe for several days to come. You must consider that I am here in that celebrated country for fruits, Touraine, which is the centre of France. They were much more backward in those countries I had just left and mentioned above, and in some parts of which wine is made in quantity.

You know how uncommonly severe and long was last winter in the state of New York, and I must observe that in this country it was one of the mildest; and the spring very fine, as well as the summer; this last season was, however, rather too dry. I was still more astonished at the comparative quickness of the growth of the vine, and the abundance of its production. It is so much in our favor, that I not only created wonder, but yet a sentiment bordering upon entire incredulity, when I mentioned the produce of a cutting planted along the house of Major Brown, late in 1827, and which had produced above one hundred fine clusters, perfectly ripe in the middle of September, 1830, and more than three hundred the following year; at the same period, equally good and fine flavored; a fact which has been well ascertained by the agricultural society of the county, and published afterwards in their transactions.

My great objection and I must say the only one which I had, and even published formerly, to the cultivation of the vine, with a view of making wine, is removed by the happy result of many inquiries and observations I have made, in examining attentively a method very different from the one which is uniformly adopted in all the vineyards of the middle and northern parts of France. There nine-tenths of the work, at least, is made by the hand of man, and part of it so painful and hurtful to the body, as to injure

materially the workmen; while in many parts of the south, and in some parts of Switzerland, where very good wines too are made, the most painful and more laborious part of the cultivation of the vine is achieved by the work of horses and cattle. The difference is such in favor of this country, between the two methods, that I do not hesitate to say, that every thing considered and calculated, this last method, with some improvements I will suggest, will not occasion you more expense than in France, to produce the same quantity of wine that would be obtained by the other method, which would cost you nearly three times as much as in France. This result is not only occasioned by the difference of the price of labor of men in the two countries, which in the preferred method is substituted for the greatest part, by the work of animals, that do not cost more in the state of New York than in France, and which can be fed cheaper; but because this preferred method owes principally its greater produce to its having a much greater proportion of land consecrated to the same quantity of vine-stalks, and that the land is considerably cheaper than here. Mr. Thiebault in comparing the two methods, to prove the immense advantage of the one he recommends, does not calculate the produce of an acre, but of the number of stalks. He says "that 2000 stalks trained according to this method, will produce nearly 26,000 gallons of wine; while on the other hand, 6,000 stalks trained in the ordinary way, produce, in common seasons, only from 750 to 1300 gallons, and in the very best seasons only about 2600 gallons." This enormous difference of thirty to one, I do not warrant, but only that there is a considerable one. Mr. Thiebault adds, that the increase in quality is also considerable.

Considering the comparative value of the land you would appropriate to the cultivation of the vine, with the same nature of land in Europe, and that there is a difference of at least nine-tenths in favor of the United States, I would propose an altogether different and more economical method in the first planting of the vine. I would set the roots and wooden posts a rod apart, instead of eight feet, as recommended by Mr. Thiebault, leaving as he does, the space between for the cultivation of grain or other productions, as preferred by the farmer. The trenches two feet broad and one foot deep, should be made with the plough and the scraper, which can be equally useful and convenient in covering the roots. Some alteration and economy could be made in the hand labor, when we take into consideration that a considerable part of it can be done by children during the vacations. On the line of that plantation I would recommend planting, in an eastern and western direction, a mulberry tree alternately with the grapevine. The wooden post will for several years be the supporter of the grapevine, but it will probably be rotten and rendered useless when the vine will have sufficient strength to need no support for its stalk, but would require some aid to keep its lateral branches in the desired position. The mulberry tree will then answer the purpose: It must be well taken care of at all times, and will pay not only the expense but yield a handsome benefit for those who will pursue the cultivation of silk, or who have in their neighborhood some one cultivating it. At all events, their cattle would relish that food which would come for them in a very good season. The tree must be trimmed in such a way as to have one single stock and a very small head, which when arrived at the height of about eight feet, must be regularly trimmed twice in the fine season, when its foliage is most suitable to the feeding of worms. In that way the mulberry will give no injurious shade either to the vines or to the grain or plants which are to be sown between the ranges. You will observe that in that way of planting and cultivating the vine, the cattle, as I have stated in the beginning of this article, will do the essential part of the work; and that they not only afford the greatest help for cultivation, but yet come in for the hardest share at the

time of collecting the fruit. I will one day give more details upon what is to be done in the years which will follow the planting and first growth; and you may rely upon my readiness to transmit to the society what further information they can ask from me. I intend to examine more minutely this kind of cultivation, and ascertain as near as I can the real produce. Meanwhile, I think the society may boldly recommend the cultivation of the vine, chiefly in the west and north of the state. To support this advice I cannot better conclude this article than by quoting, what I notice with pleasure, in a letter I have just received from the respectable secretary of the agricultural society of Jefferson county. Among the different valuable details he gives me of the cattle show and fair which took place the 26th September last, I find the following: "A curious exhibition of the process of silk-making was interesting; and Dr. Guthrie accompanied his specimen of grapes with a letter, stating that the culture of the grape was as easy and certain in this country as that of raising apples, or any other of the vegetable productions."

CULTURE OF SILK—The next important article is the culture of silk. All I have seen and heard upon that subject, since my arrival in Europe, confirms me in the opinion, that the United States in general are as well if not better adapted to the cultivation of the mulberry and the culture of silk, than the most favored countries on this side of the water. The cocoons that we raised last year at Le Raysville, with so little trouble, and such an imperfect knowledge of the proper management of this delicate worm, have been much admired by those capable of judging, to whom I presented them for examination, and the silk thought of the very first quality. I have ascertained that in the duchy of Bade, they rear the mulberry tree in very indifferent soil, rather poor, and cultivate the silk with success. Certainly where the worms are educated, the season is far from being as favorable to them as it is in the north of the state of New York. I hope that the efforts of the society for encouraging the culture of silk will have been successful, and I am very anxious to see the report which will be made to the society on a subject of such vital importance.

ON PAINTING HOUSES.

Starrington Farm, Feb. 12, 1833.

Sir.—We use paint on our wooden buildings with two objects: first, ornament; second, durability. Was oil used by itself, without any coloring matter, the wood would be made more durable than it is with paint; but as ornament is a considerable part of the objects of painting, and as the addition of paint to the oil, when properly prepared, does not very materially injure the preservative qualities of the oil, the ornamental effect of the coloring matter more than counterbalances the injury it does. Paint, when properly prepared, therefore, while it is highly ornamental to wooden buildings, so materially contributes towards their durability, that there is economy in using it.—But as it is generally prepared, (I may say always,) the ornamental effect of it on the outside of buildings is made only temporary, and its preservative qualities wholly destroyed. It is only necessary to look at our quickly decaying wooden buildings, with the paint washed off more or less in different places, according as it is exposed to the sun and rain, to be satisfied that the expense of painting has added very little towards preserving the building; and whether a building looks better without paint, or with paint nearly all washed off, with here and there a little remaining to show that it once was painted, taste must determine. If what I have stated be fact, that paint, as mostly prepared, is of little value, it will be well to look into the cause of it that the evil may be remedied; and if I give the correct cause, happily the evil is removed

without expense or trouble; or rather, it is cheaper to paint well than in this defective manner. We have only to leave out the spirits of turpentine, and we will have good paint. Ask the painter why he adds it to the paint, and he will tell you, to make it dry quick. This is just the same as saying, to destroy the oil, which renders the paint useless. Now let us reason upon it and see if this is correct. If we pour oil on wood it soaks into it, and after it is all soaked up, if we apply more oil it will strike still deeper and soak up more; when it has penetrated sufficiently deep into the wood as to prevent moisture from rain, &c. penetrating as deep as itself, the wood is rendered very lasting. This would be the case if a building was simply covered with two coats of oil without paint. If we give it only one coat of oil, with a sufficient quantity of paint to give it color, the wood would so quickly soak up the oil that the paint would be left a dry powder on the building, that would be easily rubbed or washed off. If we give it first a coat of oil with a little paint added to it, the oil soaks into the pores, another coat of oil with the proper quantity of paint, while the pores are filled with the recently put on or first coat, remains sufficiently long before the oil is soaked up by the pores, for a part of it to dry with the paint, which forms a permanent covering of paint. This is the advantage of giving two coats of paint; if the first coat was oil only, it would be better. When a house is thus painted, all the injury done by the paint is the oil which it retains and prevents from soaking into the wood, and this is in part, perhaps wholly, counterbalanced in forming a firm external covering which tends to exclude moisture; thus painted a building is preserved and ornamented. Now what will be the effect of adding spirits of turpentine to the oil? We know of nothing better calculated to destroy our intentions in the use both of the oil and paint than this addition of turpentine. Every housekeeper knows that if oil is on her floor, spirits of turpentine is the application to remove it. Every wash-woman knows that if oil is on her clothes turpentine is the application to remove it; and how does it remove it when the oil and turpentine are added together? a chemical union takes place and the qualities of both are destroyed, and although either the oil or turpentine by themselves when applied on wood would add to its durability, yet when added together the original quality of both are destroyed, and the application is useless, just as an acid and alkali, when mixed together, destroy the qualities of each other and the effect of neither remains. Now when a building is painted with two coats of paint to which spirits of turpentine is added, instead of the first covering of oil (which has very little paint) being soaked up, and the second covering, as the pores are already fed, soaking up the oil so slow that a part of the oil may dry in the paint, thus making a firm coat of paint on the surface, which will exclude moisture and prevent the evaporation of the oil, thus making the wood almost as lasting as time, and the color to remain as long as the wood lasts; what will be the effect of this addition of spirits of turpentine? The oil is decomposed, and instead of soaking into the wood and slowly drying in the paint to give a firm covering, it is quickly evaporated by the sun, the paint is left a useless powder on the wood; where it is not sheltered from the rain, it is soon washed away; and in places where it only gets wet without being washed off, as the qualities of the oil are destroyed, it retains moisture and hastens decay. We have only to go to a house which was painted white, and examine the somewhat sheltered spots where they get wet by showers, yet the rain does not beat upon them so as to wash off the paint, and scratch off the paint, and we will find the surface in a state of decay from the paint not excluding moisture but retaining it. When pine wood is painted it should more especially have only oil and paint without the spirits of turpentine, as there is in the wood turpentine sufficient to injure the oil. If we examine the

shingles or weather-boarding of a house; we will find wherever there is a knot or *fat place*, there the oil is decomposed by the turpentine in the wood, and the paint destroyed, even where no spirits of turpentine was added to the paint.

Does not this truth, which I believe all will allow, that turpentine makes paint dry quick, prove that instead of soaking into the wood the oil is decomposed and evaporates, show the destructive effect of this addition of spirits of turpentine to paint, and although the inside painting of houses remains when turpentine has been added, yet it would be more durable if the turpentine were left out. The oldest paintings we have appear as warm and glowing as when first executed, while the paintings of the first masters of modern times are injured, mostly as I think by the free use of turpentine. The fine paintings even of Sir Joshua Reynolds are losing their beauty. By some it is supposed that the paints used now are not as good as they were in former days. 'Tis not the fault of the materials, but the preparation. Oil, for instance, and white lead are as good now as they ever were, and were they used without turpentine or any thing else, as the painters say to make them dry, (or as we say to decompose the oil and destroy it,) would last as long and be as good as they ever were. If we calculate the annual amount of money used in the purchase of turpentine, and to this add the amount of loss from the injury it does, we will find it an enormous expense. From such trials as I have made, I believe the oil of palma christi to be superior to flax seed oil for preserving wood. If the two oils be put on wood, the palma christi oil will be found much more difficult to remove by decomposing with turpentine, which is proof it will be most durable. Palma christi oil, when properly prepared by boiling, is as clear and good as cold pressed oil. A good acre of land will produce from twenty to thirty gallons of it. Planters who wish to paint their buildings, would be able to make the best of paint oil, by cultivating a few acres of it, and when durability more than ornament is the object, as in out buildings, gates, &c. giving them two coats of palma christi oil, without paint, would have the desired effect. The posts of my pigeon house, which were dipped in hot palma christi oil before they were put in the ground, look like they would last for generations to come; while the posts about the yard, garden, &c. are considerably decayed. Was the exposed six or eight inches of shingles dipped in a hot pot of palma christi oil, the expense would be a trifle, and they would be very lasting. Some years ago, by neglect, a pot of oil, with which I was experimenting, was spoiled by burning; the roof of the house was quite low, the building being deep in the hill side, I threw the oil on the house roof; in taking this house down a few days ago, these shingles were found as sound and clear of moss as when put on, while the others were much decayed. But the durability thus obtained would not be the only object; it is known that old shingles become covered with a kind of mossy growth; this growth is nearly as quick to take fire as spunk, the smallest spark that falls upon it when dry may take fire. Perhaps nine out of ten houses that take fire from sparks falling on the roof, do so from this mossy growth, which never is produced on wood that is oiled; were shingles dipped in hot oil before putting them up, it would be a preventive from fire from sparks. A few days ago, during almost a calm, at mid day, when only a few coals were in the fire place, my house roof was discovered to be on fire. As there was no ladder nor no way of getting at the fire, it seemed as though the house would burn down. A very strong man, however, by getting in the window of a house not far off, was able to deaden the fire a little by throwing water with great strength; some drops would reach the fire; thus some little time was given for reflection. A man of great muscular strength with a small hatchet commenced cutting through the ceiling and sheeting. The fire began to blaze, the wind began to rise, all hope of ex-

tinguishing the fire was gone; he had however cut a hole through, and was able to tear off the boards and put out the fire. These shingles, upon examination, were found sound, but they were covered with this mossy growth. A very small spark must have set it on fire, for upon trial it was found almost as quick to take as gunpowder. Had these shingles been dipped in oil before they were put on the house, I would have been safe from such an accident, not only now but for many years to come.

ROBT. R. HARDEX.

(From the Maine Farmer.)

INFLUENCE OF CATTLE SHOWS.

MR. HOLMES.—In the New England Farmer of 1829, I observed the following notice:—

"That one of the firm of a house in Boston, that slaughters and packs more beef and pork than any other in New England, has said within a few days, that the improvement in the quality of neat cattle, in the last ten or a dozen years may be fairly estimated at ten per cent.—that is to say, the cattle now driven to this market will yield, in consequence of a favorable change in the frame of the animal, ten per cent. more flesh than was obtained from those which came to us twelve years ago—and the improvement he wholly and unhesitatingly ascribes to the influence of *Cattle Shows* in the different parts of the country. The single house alluded to, slaughters from three to six thousand head in a year, taking the average weight of each to be nine hundred pounds, it will be at once seen that this improvement in the quality of neat stock will amount to no less a sum than from 15 to 30,000 dollars a year, on the beef purchased by that one house—to say nothing of the pork. The improvement in swine, by a change in the breeds, is said by the same gentleman to have been quite equal to that in neat cattle."

The writer of the above article says, "he has conversed with the principal dealers in provision, and they all confirm the above account." "These are facts (says the writer) which ought to take fast hold of the public mind—they show the vast good which may be done by a little judicious encouragement. No doubt the improvement in dairies has been in the same proportion, though not so easily ascertained." From the above, it will be seen that about one per cent. a year improvement was the consequence of their Cattle Shows. Certainly, we in Maine, might equally improve our cattle and swine, if we have not. But I am happy to say, that he who looks back and reflects what our stock was at the time alluded to, must own that we have done much. Still much more is necessary, and undoubtedly will be effected by our Cattle Shows and enterprise. Yet we hear some object, because say they, "the poor have not an equal share of the premiums." Who will doubt but the poorer class are benefited indirectly, if not directly by such noble results.

If farmers who send their beef and pork to Boston market, had improved their stock for ten or twelve years previous to 1829, at the rate of about one per cent. a year, making ten per cent. and have continued to improve them in the same ratio for the four years since, which none can reasonably doubt, who knows that since that period much has been done, by importing the best breeds, crossing, &c. the improvement would now have been fourteen per cent. The farmers in Maine, it is hoped, will take courage and press on in this good and laudable affair, until they arrive to as great a measure of improvement, and thus benefit the great mass of the community.

Now I would ask your correspondent who observed that the poor were not able to be benefited by premiums, if the measures and results brought to view above, are on the whole, injurious to the poor? Do they not fair better in a rich than a poor community, where beef and pork is plenty?

A FRIEND TO IMPROVEMENT.

MISCELLANEOUS.

(From the Journal of Health.)

FOOD OF SEAMEN—PRESERVATION OF FOOD.

The question relative to the best and most convenient aliment for the nourishment of the crews of vessels, is one evidently of very great importance to every commercial community. It has consequently received from many of the maritime powers of Europe a very great deal of attention. From none more so than from that of France; to the experiments performed at its suggestion, on the most extensive scale, and under the superintendence of men adapted, as well from their scientific acquirements, as by their habits of close observation, to obtain from them correct results, we are indebted for many valuable facts on the subject of aliment generally.

The latest publication in connection with this question, is that of M. Keraudren. The following extracts from this memoir, will, we are persuaded, be, in many points of view, interesting to most of our readers.

To enable an individual, remarks the author, continually to undergo toilsome labor, and confront new dangers, courage is not alone sufficient—his body must likewise be healthy and robust. When man becomes feeble in body, he loses his energy and his boldness. Sufficient and proper food is especially necessary to the maintenance and development of his physical strength. The mariner, especially, therefore, requires a proper nourishment; for we all know what are his fatigues, and by how many perils he is constantly surrounded. When we consider that at sea his diet is composed principally of salted meat and leguminous seeds, in a dry state, we perceive how important it is that these substances should, at least, be of a good quality. To secure this has long been an object of solicitude. In 1771, M. Poissonnier Desperrieres, adjunct inspector of marine hospitals, proposed to restrict the diet at sea principally to vegetable substances. This gentleman attributing the origin of putrid diseases to the use of animal food, and considering scurvy a necessary consequence of living on salted meats, believed that by a diet chiefly vegetable these diseases would be prevented or rendered less malignant. His object would have been better attained had he, in place of dried leguminous seeds, been enabled to furnish the marine daily with fresh vegetables during their residence at sea.

The effect of the diet proposed by M. Desperrieres upon the health of the national seamen was ascertained by experiment. The frigate *Belle Poule* was provisioned accordingly, and after a five months' voyage returned to Brest, without her crew having experienced any disease, but with bodies exhibiting the most evident marks of emaciation and debility. Thus confirming a truth long known, that animal food is, in general, necessary to the due maintenance of bodily vigor in man.

Some years subsequently this subject was submitted to the examination of the Royal Society of Medicine; and we find in the volume of its Transactions for the years 1784 and 1785, a report in reply to the questions proposed by Marshal de Castries, minister of marine, relative to the nourishment of the crews of vessels. The authors of the report compared the mode of victualling the English and Dutch vessels of war. The English furnished theirs almost exclusively with salted meat, while the ordinary nourishment on board those of the Dutch was found to be dry vegetable substances. It is added that the crews of the English were most subject to scurvy, and that the disease caused among them greater ravages than among those of the former. They conclude that the substances which constitute the most healthy part of the nourishment employed by man, are the farinaceous, and hence it is the dry legumina that should

form the principal part of the diet of seamen. In general, they conceive that flesh is only a useful addition to this diet, as it aids the digestion and animalization of vegetable food. It is very probable that scurvy was found to be most frequent and severe on board the English than on board the Dutch ships; but it is not so certain that the difference in their diet was the cause of this. We have repeatedly seen the crews of vessels enter into port after long voyages, during which they have not been affected with scurvy, notwithstanding they had habitually eaten salted provision. But if the gentlemen who drew up the report referred to, had attributed the production of scurvy to salted meat badly preserved, or of an unwholesome quality, then should we have coincided in opinion with them. The dry leguminous seeds by which they propose to replace the salted food of seamen, are themselves objectionable. They are viscous and of difficult digestion: this is especially true of the dry beans so largely used at sea; while their hard skin defends them from the attack of insects, it prevents likewise the action upon them of the stomach. They possess no anti-scorbutic property. In preventing this disease they act negatively by taking the place of salted meats of a bad quality. Besides, when we consider the small quantity of nourishment contained in vegetable substances, convenient for the victualling of ships, especially in their dry state, when a great part of their mucilage is lost, and by undergoing a species of fermentation, their fecula, which is the part upon which their nourishment depends, is altered or destroyed, we shall see how little preference is to be accorded them over salted meats of a good quality, for the aliment of men subjected to the toils of a marine life. The observations of the officers and physicians of the navy were nevertheless the cause of some useful changes in the diet of the seamen. The heads and feet of the animals were rejected, as susceptible, when salted, of a rapid decomposition. Fish was likewise left out from the food of seamen, from its unwholesome properties and the disagreeable and injurious odor which it exhales in the vessels; and finally, the proportion of salted beef was diminished, and that of pork, the superiority of which had been tested, was increased. The manner of preparing these salted meats underwent, however, no change; a circumstance nevertheless exerting no little influence upon the vigor and health of those who partake of them.

"I had," remarks our author, "frequently observed, that beef when dried and hardened by salt, was deprived entirely of its nutritive properties. The flesh of pork, less solid, was therefore generally preferred; I, accordingly, with the consent of all, found fault with the bad choice made of the cattle slaughtered for the use of our ships." On examining into the manner of salting the meat, he discovered that a large amount of common salt was used, but no saltpetre, and a pretended anti-scorbutic mixture was added to each barrel of meat composed of alum, gum tragacanth, and madder, which latter accelerated an unwholesome change in the meat, and gave it a filthy and disgusting appearance. In consequence M. Keraudren obtained an official order directing the use of less salt, the addition of nitre, which besides preserving the meat gives it a pleasing vermilion tint, and the disuse of the anti-scorbutic mixture, in the preparation of the meat for the supply of the French navy.

The use, he remarks, of meat properly salted is not so unwholesome as has been supposed—it is not alone the cause of scurvy. Nevertheless, the means of preserving meat without the use of salt will be an important discovery. To this end the Society of Encouragement have proposed a prize; for which several essays have been offered. Appert suggested to partially cook the food whether vegetable or animal, and to put it afterwards in vases perfectly closed, and to be then immersed in water the heat of which is to be raised to the boiling point. In these vases, however, the substances were found to undergo more or

less change; and the plan is altogether incapable of being applied to the victualling of a ship or squadron. It affords, notwithstanding, an admirable means of preserving food for the sick, and in the French navy has been adopted for that purpose. Meat suspended in a current of air, dries without putrifying—but in European climates, when conducted as it must be in chambers or magazines, it acquires always a disagreeable flavor. When meat is exposed to a free current of air, the watery juices, which in its recent state cause its suppleness and increase its nutritive properties, evaporate, and it becomes dry and solid. When dried by heat it is the same. Meat thus prepared will not undergo putrefaction so long as it is kept from moisture. In drying, however, the meat, particularly beef, loses in great part its osmazone or that balsamic property to which it owes its taste, and which renders it so much the more digestible and nutritive. Meat when dried to a certain extent is likewise rendered more liable to imbibe the moisture of the atmosphere, and in this manner to become again susceptible of decomposition. If desiccation has been carried too far the animal fibre will not any longer admit the water, and will retain its hardness after boiling, so that it is impossible to cook it. The point to which the drying of the meat should be carried, therefore, is that which will be sufficient to prevent its undergoing any decomposition, while such a degree of hardening is avoided by which all its alimentary properties are destroyed. The hydrochlorate of soda (common salt) is perhaps the best agent by which to produce in meat the proper degree of dryness; that salt absorbing the fluids as they escape from the meat, while at the same time its anti-septic properties are indisputable. The heat of a stove, the action of drying substances, of oil, of vinegar, and of spices, are so many means for preserving meat, which can be employed only on small masses, and are not adapted to the preservation of large quantities. It is said that the Indians have recourse simply to the use of sugar for the preservation of animal substances, but in imitating their example the English have employed the sugar only in connection with common salt and saltpetre. It is then, after all, by salting alone, that we have it in our power to preserve for any length of time animal food, in a condition which renders it fit for the nourishment of man; and in quantities adapted to the victualling of an extensive population, of an army or a fleet.

In renouncing all other means of preserving animal food, however, it is not impossible to correct the acrid nature, and to augment the wholesome properties of salted provisions. By its admixture with vegetable substances, salted flesh becomes more fresh and less stimulating; and the dried vegetables being penetrated by the juice of the meat, become more succulent and nutritious.

In February, 1823, M. Keraudren made a report to a commission of which admiral Jacob was president, on this subject, in consequence of which, not only was the union of the dry leguminous vegetables with salted meat in the same ration directed to be observed in the navy, but every morning the men are furnished with a warm breakfast, adapted to the particular climate under which they are at the time. An arrangement, the effects of which have proved of the most pleasing character.

FENCES.—These should be righted and repaired immediately after the frost is out of the ground. It is very difficult to keep board fence from leaning, or blowing down, particularly in moist ground. This we should suppose might be remedied by having the posts much larger at the bottom, tapering towards the top. In this way there may be great economy in the posts. One as now used will make two that will be more than twice as serviceable. Posts do not decay at the top, but near the ground. Let the fence be as light as possible towards the top, in proportion to the bottom.—N. F. Farmer.

Prices Current in New York, April 27.

WHITE MULBERRY SEED, &c.

Just received at the American Farmer Office and Seed Store a supply of fresh and genuine WHITE MULBERRY SEED. Also

MAMMOTH PUMPKIN SEED.

EARLIEST FRENCH CABBAGE do.

EARLY FRENCH, or PARIS WHITE ONION do.

ACORN SQUASH do.

Together with a complete assortment of Fresh Garden Seeds, including those raised by the United Society of Shakers at New Lebanon, N. Y.

I. I. HITCHCOCK.

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals,—viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	300
Do 2 " " Do "	250
Do 1 1/2 " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each.

Half Blood and upwards.—A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenths Durham Shorthorn very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$100.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address I. I. HITCHCOCK.

Amer. Far. Office.

PUBLIC SALE OF DURHAM SHORTHORN-ED CATTLE AND HIGHLY IMPROVED SHEEP.

Will be sold on Wednesday, 29th day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd, the highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEIFERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young Lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand.

DAVID MEADE, Administrator.

April 5,—81

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at 75 cents per bushel.

I. I. HITCHCOCK,

American Farmer Office and Seed Store.

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale.

Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life,) is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also,—A young JACK, a son of Don Carlos, 4 years old, 43 inches high, well made, stout and promising, of same color as his sire—price \$150.

Also,—A full sister of the last, 3 years old, 44 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

I. I. HITCHCOCK,

Ap. 26—11.

Amer. Farmer Establishment.

200,000 WHITE MULBERRY TREES.

The Subscriber has on hand and for sale 200,000 White Mulberry Trees of two and three years' growth, which have been transplanted, are in a healthy and thrifty condition, and which he offers for sale at \$1.50 and \$2.00 per hundred, delivered at the nursery.

Also, a few of the *Morus Multicaulis*, or Chinese White Mulberry.

ASA BUTLER,

Suffield, Connecticut.

P. S. All orders (post paid) will be punctually attended to. April 12,—61.

SINCLAIR AND MOORE'S NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Bushes, (among which is the much admired Greville,) double Altheas, Honeysuckles, Corcorus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Alanthus, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets. Feb. 22.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Scythes, Grain Cradles, Scythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—There are very few changes to notice in the produce market. A few sales of Howard street flour have been made at our quotations, though speculators generally decline dealing at above \$5.25, while holders generally prefer holding on unless they can get \$5.37 1/2. Fresh ground city mills sells readily at our rates.

TOBACCO.—Seconds, as in quality, 3 09 a 5 00; do. ground leaf, 5 09 a 9 00.—Crop, common, 3 00 a 5 00; brown and red 4 50 a 6 00; fine red, 6 00 a 8 00; wrappery, suitable for segars, 5 00 a 15 00; yellow and red, 9 00 a 15 00; yellow, 16 00 a 20 00.—Line yellow, 18 00 a 25 00.—Virginia, 4 00 a —.—Happahannock, 3 00 a 4 00.—Kentucky, 3 50 a 5 00. The inspections of the week comprise 837 lhd. Md.; 141 lhd. Ohio; 16 lhd. Vir. and 4 lhd. Penn.—total 1001 lhd.

THE FARMER.

BALTIMORE, FRIDAY, MAY 10, 1833.

THE DROUGHT—We have never known so long and severe a drought at this season of the year, as that which is at present parching the earth in this vicinity. It is upwards of three weeks, since we have had any rain, and double that time since the earth has been even tolerably moistened. All early vegetables are suffering greatly, and if prompt relief, in the shape of copious rains, is not soon received, all will be lost. The grain crops appear to be doing tolerably well. The drought appears to be as severe at the south and east of the Allegany mountains, generally, as with us. The following paragraphs show the state of the weather in the north:

FIRES IN THE WOODS.—A letter from Saratoga county, dated the 2d inst. says, "It is exceedingly dry in all this region. I learn that fires are raging extensively in the woods on Lake Champlain."—Another letter of the same date from Green county, mentions that much damage has been caused by fires in that and Sullivan county.

Brattleboro', Vt. April 30.

THE WEATHER.—At the date of the present writing, (12 o'clock, noon, April 30,) our entire stock of living animals, man and beast, is in a suffering condition from the unexampled warmth and sultriness of the weather. For some time past the season has been uncommonly dry, and at this time it appears as if the sun was about to lick up the last drop of moisture which lingers in our parched fields. We heard yesterday of five instances in which cattle at work dropped down and expired under the effects of heat, and there is reason to fear that the mortality among cattle from that cause has been very extensive. The mercury in the thermometer stood yesterday at noon at eighty-five degrees, and it is now at eighty-four.

Montreal, April 30, 1833.

Yesterday the heat was as powerful as might be expected in the dog-days; the thermometer averaged 85 in the shade, with an oppressive hot wind, rendered more disagreeable by the dust with which every pedestrian was enveloped. We never recollect a day of such steady and inconvenient warmth in the fickle month of April. This day the transition has been equally sudden, the thermometer scarcely reaching 50, the wind boisterous and cold, but the dust scarcely less unpleasant.—*Gaz.*

THE ORIENTAL CYPRESS TREE.

The Editor of the American Farmer is much indebted to Mr. Skinner for the following letter from Cum. Porter.

DEAR SKINNER:

Pera, Jan. 30, 1833.

I send you some of the seeds of the oriental cypress tree, with which the Turkish cemeteries are decorated and embellished. They are now at perfect maturity. I had them collected yesterday.

I have sent some to the Horticultural Society of Massachusetts, where, I have no doubt, they will be properly disposed of. Those inclosed I beg you to distribute; as perhaps the climate of Maryland will be better adapted to them than that of Massachusetts, though I have no doubt that the tree will flourish in both.

Every body has read of the beautiful and extensive cemeteries of Pentari, of Pera and Constantinople. It is to this tree they owe their beauty. It is not worth while to go into a minute description of it. It is sufficient to say, that it is the most appropriate tree for grave yards; and, as the question has been agitated in some of our papers, how our grave yards should be ornamented, I send these seeds.

The tree is an evergreen; the top of a beautiful

elongated conical form. It grows to a goodly size, and of an enormous height, as thick as they can stand; and may be propagated from cuttings as big round as the leg or arm.

I never pass one of our grave yards without a kind of horror at the idea of being deposited there. I never enter a Turkish cemetery without feeling gay where all is gaiety; for they are places of resort for amusement of Turks, Jews and Christians. There is no place more gay of a summer evening than the *Champ des Morts de Pera*. This is all owing to the cypress tree. With us, the deserted and neglected grave yard keeps us in constant terror of death. Here death has no such horrors; the lovely groves of the cypress and the gaiety of the place reconcile us to it. Whether it is best, to live in constant dread of death, or to be perfectly familiar and reconciled with it? If the latter, decorate the grave yard and plant the oriental cypress: *the grave will lose its victory, and death his sting.*

Yours, truly,

DAVID PORTER.

P. S. Pray, how did you dispose of the pine seed? If those I sent you failed, let me know, that I may send you more. They make great use of them here in all their cookery and confectionary. They are "delightful," as good Mrs. F. used to say, and I hope still lives to say.

[None of the seeds of the stone pine vegetated.—*Ed. Am. Farmer.*]

BARNEY'S BAKEWELL SHEEP.

EXTRACT OF A LETTER DATED,

Girard Farm, near Philadelphia, }
April 30, 1833. }

"I feel more than ever assured, that my stock of sheep is well worth the attention of any gentleman wishing to improve their flocks of sheep, particularly so, when I have had the gratifying statement from a man of veracity, whom I directed to purchase sheep for me in England. He is of high standing, and a good judge—and after looking over a large part of the sheep districts of England, the last fall and winter, for the purpose of purchasing, he arrived in the packet ship *Montezuma*, the 17th inst. and tells me on his word and honor, he could not find any better, or as good as those I have already, so that he concluded not to bring any with him. I had sixteen wethers slaughtered in Philadelphia, last January—allowed by the best judges to be the best and fattest ever killed for that market—two saddles sent to New York, and one sheep to Washington; and as far as I have heard, every good judge of the quality of sheep and mutton, pronounced them the best they have seen.

"JOHN BARNEY."

RURAL LABOR

BENEFICIAL TO PROFESSIONAL MEN.

A clergyman residing in the northeast part of Mass. in a letter to one of the editors, thus speaks in the commendation of rural labor; "I cultivate but a small piece, and this only as a matter of taste and amusement. I think the personal attention which I have given to my garden has been of the highest benefit to my health; and thereby enabled me to go through labors connected with my business which I should otherwise never have been able to perform. I spoke of cultivating as a matter of taste and convenience. I ought to say, that as my trees and vines come forward, I begin to realize the truth of the adage, that 'in all labor there is certain profit.' And I cannot refrain from observing how different would be the situation of any clergyman, I may add lawyers, physicians, merchants and mechanics, would they from the commencement of business direct some of their leisure hours to the cultivation of a garden and a fruit lot."

This worthy man (and he is not the only one of the profession that is in this way worthy) has done much to awaken a taste for improvement in rural

labor among his flock; and we have read with interest his communications to the Agricultural Society of his county. Such a man is pre eminently useful; and we publish the extract without permission, in hope that his example may be profitable to others. The clergy certainly have it in their power to improve the temporal as well as spiritual interests of those around, and nothing goes further in either than good example.

COBBETT'S COTTAGE ECONOMY.—Cobbett is one of the best writers of English now living, and whatever subject he writes upon, he is sure to win the reader's attention. Open this book where you please, and if you begin to read a paragraph, the chances are ten to one, or as a rata-baga to a grain of mustard seed you will not stop till you finish it. Take this for an experiment.

MUSTARD.—Why buy this when you can grow it in your garden? The stuff you buy is half drugs and is injurious to health. A yard square of ground sown with common mustard, the crop of which you would grind for use, in a little mustard mill, as you wanted it, would save you some money, and probably save your life. Your mustard would look brown instead of yellow; but the former color is as good as the latter; and, as to taste, the real mustard has, certainly, a much better than that of the drugs and flour which go under the name of mustard. Let any one try it, and I am sure he will never use the drugs again.—The drugs, if you take them freely leave a burning at the pit of your stomach, which the real mustard does not.—*Boston Courier.*

(From the York Republican.)

PROSPECT OF THE WHEAT CROP.

A ten days' jaunt across Frederick and Washington counties, in Maryland, and into the upper part of Virginia, gave us an opportunity of observing the very fine region of country with which the citizens of that section are blessed. We could not but regret the slovenly appearance of the wheat fields, with but rare exceptions. This evil arises from their system of large landholding, and sowing wheat upon corn ground. Many of their wheat fields present bare stripes every twenty feet, which extend across them, and are caused by setting their corn or tops upon the ground, and not having or taking time to remove them; and thus so much ground is lost by being left unsown and unploughed. Upon the whole, although these citizens of our common country are equally blessed with us in the possession of as fine rich lands as any in the world, yet for the causes above mentioned, their farms do not present the thrifty and neat appearance of the good lands east of them. Indeed, within a few weeks past, we have had opportunities of seeing the condition of the wheat prospect in parts of Chester, Lancaster and York, in Pennsylvania; of Frederick, Washington and Baltimore counties, in Maryland; and also a part of Virginia, and no where does it present so promising an appearance as in this county: and further, we may say, without boasting, that no where did we see so beautiful a valley as that in which we reside. Its high state of cultivation, its extraordinary fertility, and above all, its beautiful prospects and salubrity, render it most certainly a place where our first parents might contentedly have dwelt.

SEWING ON GLAZED CALICO.—By passing a cake of white soap a few times over a piece of glazed calico, or any other stiffened material, the needle will penetrate with equal facility as it would through any other kind of work. The patronesses of the School of Industry pronounce this to be a fact worth knowing; the destruction of needles in the ordinary way occasioning both loss of time and money.—*Taunton (Eng.) Courier.*

The heart, by its muscular contraction, distributes two ounces of blood from seventy to eighty times in a minute.

AGRICULTURE.

(From the New England Farmer.)

AN ADDRESS

Delivered before the Worcester Agricultural Society, October 10, 1832; being their Fourteenth Anniversary Cattle Show and Exhibition of Manufactures. By WALDO FLINT, ESQ.

Agriculture, in its simplest form, was probably the first, and it is undoubtedly the most important, occupation of man. It lies, in fact, at the foundation of civilized society. The spontaneous productions of the earth, especially when aided by contributions from the air and the deep, may, indeed, afford a precarious subsistence for a small population, scattered over a wide extent of territory; but still, man, without other and surer means of support, ever has been, and ever must be, savage man. The degree of civilization and refinement to which any tribe or nation of men may have attained, may be pretty accurately measured by the advance they have made in the agricultural art. I do not mean of course, to be understood as saying, that agriculture can flourish alone, without the aid of the mechanic arts, but I do mean to say, that while all the arts mutually aid and assist each other, agriculture must take the lead in the march of improvement.

Hence we find, that under all well ordered governments, its improvement has always been an object of peculiar interest and regard. What raised ancient Egypt to the height of her grandeur? Not the fertility of her soil alone, enriched as it was by the overflowings of the Nile; a rich soil is no blessing to an idle population. It was the laborious industry of her inhabitants, encouraged and protected by sound maxims of state policy, which made her the granary of the world. The Nile has continued, down to the present time, to make its annual contributions, and, while the monuments of her foolish pride still stand the wonders of the world, her fertile plains are trampled upon by the feet of reckless barbarians.

Rome, too, in her best days, was not less distinguished by her skill in the peaceful arts, than for her military prowess. Her best military commanders were also her best practical farmers; and "to neglect the cultivation of a farm was by them considered an offence, which merited the chastisement of the censor."

When the great northern Hive sent forth its swarms of barbarians to ravage and possess the provinces of the Roman empire, agriculture not only fell into neglect, but came to be considered a *menial* occupation. The only honorable profession, in those unsettled times, was that of arms. The lands were hunted out by the conquering generals, in large districts, among their favorite officers, who again subdivided them among their followers, and all were held, originally, on the condition of rendering military service to their respective superiors. Those who were employed in husbandry, were liable to be called away, at any moment, from their business, to attend upon their huge lords, and it can be no matter of wonder, therefore, that the art should have become nearly extinct.

When in the progress of time, the temper of the people had become more peaceful, and the tenure, by which estates were held, more secure, agriculture began again to revive. But, then, out of the feudal system, to which I have just referred, arose the laws of primogeniture and entails, by which family dignity and pride were to be sustained at the expense of justice and sound policy,—the evil effects of which on agricultural improvement are felt, even in the most enlightened states of Europe, at the present day.

Agriculture has never, since the fall of the Roman empire, or at least never until recently, except perhaps in China and some other portions of Asia, assumed its proper rank among the arts of life. It has generally been considered an occupation requiring less of science and skill, than almost any other art. It is

true, the mere manual labor on a farm does not call for extraordinary skill; but to superintend and control all the various operations of farming, so as to make it a profitable business,—to adapt the crop to the soil and the climate,—to provide for contingencies and change the mode of cultivation, when circumstances require it,—all this, it seems to me, demands great judgment and discretion, as well as much science and skill. Dexterity or expertness is all that is necessary in many of the mechanic trades, and this may be acquired by practice. So practice will generally make a good mower, a good reaper, a good ploughman, but neither of these, nor all combined, will alone constitute a good farmer. In agriculture, *nature* produces every thing, and it is the business of the husbandman to direct her operations. He cannot, as may be done in some of the mechanic trades, follow on, year after year, in any one beaten track. He must study, and study diligently, the nature of the soil he has to deal with; he must watch its changes, and trace these changes, if he can, up to their causes; so that he may learn how to preserve his lands in health, or, if they become diseased, what remedy to apply in order to restore them. Every year's observation should add something to his stock of knowledge. The productiveness of the earth is influenced by a great variety of circumstances, which wholly escape the notice of the careless observer; and the farmer who should, in spite of experience, persist in cultivating his lands in a particular manner, either because his father did so before him, or because he may himself have found his course of husbandry profitable under different circumstances, would be very like the physician who should, on all occasions, turn to his book of recipes and make out his prescriptions, without studying the constitutions, and inquiring into the particular habits of his patients.

In order to be accomplished in the art, the farmer should have some acquaintance with the *science* of husbandry. Not that every farmer is expected to be a philosopher, and "understand all mysteries and all knowledge;" but he ought, certainly, to know something of the compositions of soils and of the nature and properties of the different kinds of manures, that he may be better able to judge what substances are wanted to preserve or increase the fertility of his lands. This he may indeed learn from experience, and experience, after all, is the farmer's only sure guide; but reading will supply him with hints which he may find exceedingly useful in conducting his own experiments. The practical agriculturist, I know, has little leisure for study; but he can find time enough, every week in the year, to read the *New England Farmer*; and the long winter evenings will afford him leisure, if he choose so to employ them, to become acquainted with more voluminous publications on the subject. I have said, *experience* is the farmer's only sure guide; but he will not be governed by his own experience merely. He will avail himself of the experience of his neighbors also; and will adopt in the management of his own farm, any improvements which they may have introduced in the culture of theirs. For the same reason, he should enlarge the circle of his inquiries, not confining himself to his own town, or state, or country. The farming tools and agricultural operations of Great Britain are very similar, in most particulars, to those of the United States, and many valuable treatises on the subject have been published there, which are now accessible to the American farmer. Some of these will give him much useful information; and his own good sense will teach him to adopt or reject their mode of husbandry, as he may find the same applicable or otherwise to the condition of our own country.

In this country, from its first settlement, agriculture has always been considered an honorable, as well as most useful occupation. Indeed, up to the time of the revolution, it constituted almost the sole employment of the inhabitants. Manufactures, except the common household manufactures which are

found in all new settlements, there were none: of commerce, there was next to nothing; and I cannot learn, that any of the most common mechanic arts were cultivated any farther than was absolutely necessary. It was the policy of the mother country to supply her colonies with every article which she could make at home. Her motherly kindness went even farther: she could not consent that her children here should have the trouble even of transporting the articles which her bounty supplied them with. And, in return for all this goodness, she only required that they should pay her liberally for her goods and their freight, in any articles of produce which she wanted and could not raise on that portion of the farm which she carried on herself. I take the liberty to quote the preamble to an act of Parliament, passed 1663, for the purpose of presenting, in a clear light, her disinterested regard for the prosperity and welfare of her colonies.

"In regard to his majesty's plantations beyond seas, are inhabited and peopled by his subjects of this his kingdom of England—for the maintaining a greater kindness and correspondence between them, and keeping them in a firmer dependence upon it, and rendering them yet more beneficial and advantageous unto it, in the further employment and increase of English shipping and seamen—vent of English woollens and other manufactures and commodities, and making this kingdom a staple, not only of the commodities of these plantations, but also of the commodities of other countries and places, for the supplying of them. Be it enacted," &c. "The only use and advantage of American Colonies and West India Islands," it was said, "was the monopoly of their consumption and the carriage of their produce." England has continued, even since partition was made and the late colonists have managed their portion of the farm in their own way, to manifest the same watchful care over the interests of her children. She says now, as she always used to say, that it is giving ourselves quite too much trouble to manufacture our own clothing, and is perfectly willing and ready to supply us with whatever we want in that line, ready made; and will take, in exchange, our cotton, rice, tobacco, and indeed, any thing else, which she must have and cannot raise for the supply of her own wants. She has allowed us, occasionally, to truck a little with her West India Islands, when they have chanced to be in a state of starvation; and has recently consented that we may go there when we please, without molestation; on certain *conditions*, however, which, as some think, give her the best end of the bargain.

But I have dwelt longer, than I purposed, on the Colonial policy of England. I intended only to have made a passing remark—that the policy, she adopted in relation to these colonies, with the expectation of making them more dependent upon her, and of hindering them more closely to her, was, probably, the best which could have been devised, to prepare them, in due time, to assert and achieve their independence. Had they been left free to push their fortunes in any channel, into which inclination might have led them, it is a fair presumption, that they might have remained, to this hour, an appendage of the British Empire. The Fathers of New England came to these shores deeply imbued with the love of liberty,—"not like other men, whom small things could discourage or small discontents cause to wish themselves at home again," and the employments, in which they here engaged, were well calculated to fix and perpetuate this sentiment in their hearts and in the hearts of their children, while at the same time, they gave them the nerve and the muscle, which were necessary to brace them for the contest.

When our independence was established and the country had, in some measure, recovered from the effect of her seven years' struggle to secure it, a thousand new channels were opened to the enterprise of our citizens. Large fortunes were, occasionally, accumulated in the course of a few years, and the young

and active and enterprising were tempted by the prospect of wealth, quickly, and as they supposed easily, acquired to engage in foreign commerce or domestic trade rather than to secure a competency by agricultural pursuits, in which their gains, though more certain, would be less rapid.

An old English writer defines *English* gentlemen thus—"As for gentlemen, they be made good cheap in this kingdom; for whosoever studieth the laws of the realm; who studieth in the universities, who professeth the liberal sciences, and to be short, who can live idly and without manual labor, he shall be called master, and shall be taken for a gentleman." In this country; for a while subsequent to the time of which I have spoken, the feeling, I suspect, was common with too many, that it was more respectable to live by one's wits, than by manual labor; as if honest industry could ever fail to secure esteem and command respect! The young men were too easily persuaded, by the prospect of light labor and great gains, to desert the country for the city, where, if they were fortunate enough to preserve their moral purity in the midst of temptations, the chances were greatly against their attaining the object of their desires. It may be safely asserted, that the industrious and economical farmer or mechanic is sure of a competency, in this country, while in the possession of health. But let a man walk through the business streets of one of our commercial cities, and after the lapse of ten or even five years, let him return and take his walk again through the same streets, and inquire what proportion of the former occupants are still there, prospering in business, and he will, probably be surprised to learn, that there are so great uncertainties in trade. I have heard it estimated by persons of observation, and competent to form a correct opinion on the subject, that of the young gentlemen who commence in the metropolis of our own state, not one in five meets with so much success as to induce him to continue his business. The career of many early terminates in bankruptcy, and of these, notwithstanding the well known liberality of the merchants of that city in discharging from further liability those who honestly surrender their property for distribution among their creditors; not a few continue, for the remainder of their lives, in a state of penurious embarrassment, which necessarily precludes them from obtaining any thing more than a bare subsistence. The same kind, though not the same degree, of uncertainty attends the business of merchandizing in the country. The reason is obvious; the merchant or trader necessarily deals much on credit, and if his business is large, his credits must be proportionably extensive; so that he stands responsible not only for his own honesty and good management, but for the skill and integrity of his customers. It is not thus with the farmer. His debts may, indeed, refuse or be unable to pay, but his lands cannot take wings and fly away. They at least will stand fast; and he has the sure word of Providence, that seed time and harvest shall never fail. He deals with fewer individuals than the merchant or mechanic, and can, more easily than they, select his own customers. The productions of a farm, too, are always saleable at fair market prices; for man must eat, though he will not work, and can no more

—"cloy the hungry edge of appetite,"

"By bare imagination of a feast,"

Than "he can hold a fire in his hand,

"By thinking on the frosty Caucasus."

Besides, there is seldom any necessity, that the farmer in New England, should sell on credit, unless he choose to run the risk of loss for the sake of getting something above the market price for his commodities. Neither can he be subjected to much expense or loss of time in sending his produce to market; for the busy manufacturing villages, which are springing up on every hand around us, as it were, by enchantment, will always furnish him, if they are suffered to con-

tinue and prosper, with cash customers for all his surplus productions.

If money, then, be not the supreme good; if health and a competency are to be preferred to greater wealth, earned as it often must be, by anxious days and sleepless nights, let not the farmer repine at his lot. He may work harder than some who are engaged in other pursuits; but his sleep will be more sound and refreshing. He may not be able, after a life of industry, to point to heaps of hoarded gold, as the fruit of his labors; but, if true to himself and duty, he will leave a better legacy to his children. They will have been trained up to habits of industry, temperance, sobriety, virtue, and he will himself be gathered to his fathers a shock of corn fully ripe."

I have gone on the assumption, that the profits arising from agriculture, though more certain, are not so great as those derived from some other branches of industry. It would appear, however, from a document published among the Collections of the Historical Society, that there *was* a time, immediately after the settlement of our ancestors at Salem, when the farmer could have had no good cause for complaint, either on account of the barrenness of the soil, or the smallness of his profits. It is entitled "A short and true Description of the Commodities and Dis-commodities of New England's Plantation, written in the year 1629, by Mr. Higgeson, a reverend Divine, now there resident." "The fertility of the soyle," says Mr. Higgeson; "is to be admired at, as appeareth in the abundance of grasse, that groweth everie where, both verie thicke, verie long, and verie high in divers places.—It is scarce to bee beleaved how our kine and goates, horses and hogges, doe thrive and prosper here and like well this country. But the abundant encrease of corne proves this country to bee a wonderment.—Thirtie, fortie, fittie, sixtie are ordinarie here; yea, Joseph's encrease in Egypt is out-strippt here with us. Our planters hope to have more than a hundred fould this yere,—and all this while I am within compassse. What will you say of two hundred fould and upwards? It is almost incredible what great gaine some of our English planters have had by our Indian corne. Credible persons have assured me, and the partie himselfe avouched the truth of it to me, that of the setting of 13 gallons of corne bee hath had encrease of it 52 hogsheads, every hogshead holding seven bushels of London measure, and everie bushel was by him sold and trusted to the Indians for so much beaver as was worth 18s. and so of this 13 gal. of corne, which was worth 6s. 8d. he made about 327 pounds of it the yere following, as by reckoning will appeare: where you may see, how God blessed husbandry in this land."

Nor was the fertility of the soil the only thing in the country, about those days to be admired at. The astonishing increase of population might equally well prove it to be a wonderment. At a General Court holden only five years after the settlement of Boston—"Roxbury and Watertown had leave to remove, whether they pleased, so as they continued under this government." "And the occasion of their desire to remove," as Gov. Winthrop's Journal informs us, "was—for that all the towns in the bay began to be much straitened by their own nearness to one another, and their cattle being so much increased." I have already made the remark, that agriculture has always been regarded in this country as an object of special interest. The vast extent of our territory, much of which is yet to be peopled by civilized men—embracing almost all varieties of soil and climate, and capable of yielding almost all the known productions of the earth seems to indicate, that this is to constitute the great business of its inhabitants. The sparseness of our population, compared with that of most countries of the old world, and the consequent low price of land and high price of labor have hitherto prevented our pushing the art to a high degree of perfection.—Where land is high and labor cheap, the true policy is to make the land produce to the full extent of its

ability. Our policy, on the contrary, has been to make the most we could of *labor*. The population of our own state has now become so dense, and the price of land so much increased, that our interest requires, that we should be making progress in agricultural skill, unless we are willing to be undersold, in our own markets, by those whose lands cost less than ours and who happen to have a more kindly soil to cultivate. Much has been accomplished within the last few years. The formation of Agricultural Societies, and the introduction of Cattle Shows among us, have already produced very important results, and, probably, in no section of our Commonwealth, have the advantages, to be derived from them, been more distinctly manifested than in our own country. We pride ourselves—and we are, sometimes, perhaps, a little more boastful on this subject than is quite becoming our modesty—in being able to make as goodly an exhibition of cattle as can be made in any other county. That we are able to make so fair an exhibition—is to be attributed mainly, I think, to our annual Cattle Shows. They afford us all an opportunity of seeing a variety of breeds together, and of comparing them with each other, and of forming an opinion of their comparative merits. An improvement perhaps even greater, has been made in our sheep, and one still more striking in our swine. The products of our dairies, too, though they have, for many years sustained a high reputation, have fully kept up with the improvements of the age. Our farming tools have undergone a similar change. The plough, the shovel, the hoe, are all much more convenient and effective, as well as more slightly implements than they were only a few years since. The whole aspect of things is changed for the better, as must be apparent to every person who merely passes through the country. Larger and more commodious barns are seen rising on the ruins of the old ones.—Dilapidated fences, prostrate gates, broken barn doors, creaking mournfully on a single hinge, are now comparatively rare occurrences, and we are beginning to learn, that there is no economy in turning out our cattle and our hogs (would, that I could say, geese, also,) into the highways, to pick up a miserable living at the expense, and to the great annoyance of the public. An air of neatness and comfort about our farms and farm-houses, is beginning to be more generally valued and cultivated.

But notwithstanding all our boasted improvements, and though we live, as every body says, in a most "extraordinary age," I cannot but think, that our ancestors had in some respects, much more correct notions of what is comfortable than any of their descendants. Who does not love to visit, on a warm summer's day, some of our oldest agricultural towns, and enjoy the coolness and serenity, which are every where to be found beneath the shade of their wide-spreading elms? It is very much the fashion with us, to erect our houses on the highest points of our own high hills, and there they are too often suffered to stand in solitary grandeur, without so much as a single tree of any kind to guard them against the burning suns of summer or the driving storms of winter. Without regard to appearances, without regard to personal comfort, it does seem to me, that economy alone, a bare wish to save money, should be a sufficient inducement to us to plant forest trees in the neighborhood of our houses and out-buildings. They absolutely cost nothing. Every farmer's wood-lot will furnish him with all the necessary varieties, and a few hours' labor, on a lowering day, in transplanting them, and a very little attention afterwards in guarding them from injury while young, are all that is wanting to insure their growth. They will furnish a refreshing shade both for man and beast, during the noon-tide hours of heat and rest from labor; they will give an agreeable coolness to our houses in summer and will add to their warmth in winter, beside saving many a little charge for broken windows and shattered window blinds.

In another particular, I think, we have not followed up the example set us by our forefathers—I mean, in the cultivation of fruit trees. I am happy, however, to admit, that we have been of late improving in this respect. Great praise is due to the Massachusetts Horticultural Society, and to individuals in our own neighborhood, for their exertions to excite a deeper interest in this department of agriculture.—Very considerable sums are annually expended for foreign fruits, when at a trifling expense of time and money, we might supply our tables with fruits of the choicest flavor of our own raising. There is great practical good sense in the dying advice of the Laird of Dumbredikes to his son Jock: “When ye hae naithing else to do, ye may be aye sticking in a tree; it will be growing, Jock, when ye’er sleeping. My father tauld me sae forty years sin’, but I ne’er fand time to mind him.” And the advice which follows, though not altogether apposite to the subject under consideration, is certainly not less valuable: “Ne’er drink brandy in the morning Jock; it files the stamack sair.” It is sometimes said by way of excuse for not cultivating fruit-bearing trees and vines, &c. that there is little use in attempting it, inasmuch as the fruit will certainly be appropriated by those, who have not had the trouble and expense of raising it.—I know that petty larcenies of this sort are quite too common, and it is a lamentable fact, that individuals are sometimes concerned in this miserable work of darkness, who would claim the reputation of being, in their ordinary transactions, at least, “indifferent honest.” I have noticed that associations have been formed in some towns for the purpose of detecting such midnight depredators, and they will undoubtedly produce beneficial effects. Let pains be taken to bring the guilty to exemplary punishment, and the offence will soon cease to exist. At all events, let every man, who has land suitable for the purpose, when he has nothing else to do, be sticking in a tree, and, in the course of a very few years, fruit will become so common, that any man however depraved he may be, will be *ashamed* to steal it.

There is another subject, to which I would beg leave to call the particular attention of this Society—the preservation of wood lots. In many of our towns, and particularly in those where factories are located, the price of wood has risen, within the last ten years, twenty-five and even up to fifty per cent. Fuel has already become a very important item in the expenses of a family. I am not prepared to point out what should be done, but the last winter’s experience should admonish us; that all reasonable care ought to be taken to prevent the waste and destruction of an article, which is becoming yearly of more and more consequence. It is a subject alike interesting to buyer and seller. I have thought, that the owners of wood lots have, in some instances, been too anxious to realize an immediate income, and for the sake of present gains, have sacrificed much larger profits in prospect. I have thought, also, that, after a lot has been cut over, sufficient care has not always been taken, by fencing and other means, to preserve the new growth from injury. I am not competent, however, to give advice; but have felt it to be my duty to suggest this subject, as being one, in my opinion, of primary importance, for the consideration of those who understand it better than I do.

The prospects of the farmer in New England, were never, probably, more encouraging than at the present time. His Indian corn may, occasionally, be injured by an early frost, as it has been in some places this year, and as it has been in former years; but he may look forward, as it seems to me, with confidence, to a course of continued and increasing prosperity. The policy of our government in relation to the protection of American industry, it is to be hoped, is now settled; and as long as our manufacturers are able to realize a fair profit in their business, so long the farmer will find a ready market for his produce at fair prices. The interests of agriculture and manufactures, in

this section of our country, it cannot be doubted, are inseparably connected. The facilities for communication and transportation, which public spirited individuals are now opening to us, by the construction of rail roads, will greatly promote the interests of these important branches of industry. The road, which is already commenced, will place us by the cheapness and quickness of transportation, almost in the immediate vicinity of our metropolis; and another, which has been recently surveyed by enterprising citizens of a neighboring state, and which, there is good reason to expect, may, in due time, be located and constructed, will bring us into close connection with Long Island Sound. If any man can possibly doubt the advantages of an easy and cheap communication, to all branches of business, I would advise such an one to take another view of the beautiful village where we are now assembled, and then to follow the course of the Blackstone Canal to its termination at Providence, in order that his doubts may be removed. Massachusetts, though she has manifested some reluctance to engaging in public improvements of this description, and has permitted other States to get far in advance of her, will not, we trust, now that she has fairly set herself at work, be wanting in the enterprize and zeal, which are necessary to carry them forward into full and successful operation.

I have alluded in the course of my rambling remarks, to some of the moral influences of agricultural pursuits; and though I may, perhaps, have trespassed already too long on your patience, I cannot forbear to ask your indulgence for a very few additional remarks on this interesting part of the subject.

It is recorded of King Numa, “that he introduced among his subjects, an attachment to agriculture as a charm of Peace;” for, says Plutarch, “no occupation implants so speedily and effectual a love of peace, as a country life; where, without diminishing the courage and bravery necessary to defend property, the temptations to injustice and avarice are removed.”

We accordingly find, that in his reign, the temple of Janus was closed—an occurrence which, with a single exception, happened not again during the lapse of seven centuries. Nor is this peaceful disposition confined to intercourse with foreign nations. In the daily intercourse of citizens of the same State, town, neighborhood, the same disposition among the tillers of the ground is, I think, equally apparent. There is among them more of harmony and good feeling—less of personal envying and strife, and less of party discord and bitterness, than is to be found in any other profession.

Another advantage of agricultural pursuits is their happy adaptation to the formation of virtuous habits. It has been said—“An undevout astronomer is mad!” He, whose business it is to study the far-off worlds in the firmament above us—

“Observe how system into system runs,
What other planets circle other suns;”—

is to be called a mad-man, because he fails to recognize, in the wonders of nature, the existence of an all-wise Creator and Disposer—what can we say of the *infidel farmer*, whose whole intercourse is with nature in what we are wont to consider her simplest forms, and yet he cannot tell, how a single one of all earth’s various products, which he gathers into his store house, is made to grow! Surely, if true devotion is any where to be found on earth, we should expect it to burn bright and pure on the farmer’s family altar.

Again, where shall we look for genuine patriotism,—pure, unadulterated love of country? Where, if not among the independent yeomanry of the country? “The merchant,” says Adam Smith, “is not necessarily the citizen of any particular country. It is, in a great measure, indifferent to him, from what place he carries on his trade; and a very trifling disgust will make him remove his capital, and together with it all the industry which it supports, from one country

to another. No part of it can be said to belong to any particular country, till it has been spread, as it were, over the face of that country, either in buildings, or in the lasting improvements of land.” The same may be said, perhaps, with equal truth, of all other professions, except that of agriculture. The home of the farmer is on the soil which he owns, and which he cultivates for the support of himself and his family. There he expects to live, and there he expects to die, and there he hopes, will be found his descendants through a long succession of generations.

How deep, then, the interest he must feel in the welfare of his country;—how intense the desire, that she may continue to be free, and prosperous, and happy; and with what melancholy forebodings, must he witness the first gathering of clouds which threaten her with ruin!

Such clouds may now be seen rising above our political horizon. Sentiments at war with the fundamental principles of our Union are, in one section of our country, openly avowed and advocated. If they shall gain currency and spread extensively among us, the oldest of us, now here assembled, may live long enough to listen to the knell of his country’s liberty and to exclaim,—

“Had I but died an hour before this chance,
I had lived a blessed time —”

But let us hope better things. Our fathers would start from their graves, and cry—shame upon us!—There must be—there *must* be a redeeming spirit, which will save us from such utter infamy.

HORTICULTURE.

EXTRACTS

From the “*Historical and Descriptive Account of British India.*”

Our knowledge of Indian vegetation, although extending itself with a rapidity almost unexampled in the botanical history of any country, is yet extremely limited. Nor can this be a matter for surprise when we call to mind the prodigious extent of our Asiatic possessions, reaching as they do from within six degrees of the equinoctial line to the thirty-fifth degree of northern latitude, with a range of temperature from that of the torrid zone to regions of perpetual snow.

It is extremely difficult to form an estimate of the probable extent of the Indian flora, the vegetation of many parts of the country being entirely unknown, and almost every where very imperfectly explored. In fact, in the remote districts, little more has been done than to follow the courses of rivers. The herbarium in the museum of the East India Company contains about nine thousand species, including those known and described by Roxburg in his manuscript catalogue, most of which were at that time new.—Tu this amount remain to be added a considerable number of species in the collection of Dr. Wight.—It is the opinion of the latter gentleman, that when he returns to India he shall be able to collect as many species in the presidency of Madras alone as we possess at present from the whole of our possessions there. Dr. Wallich obtained, from his own personal exertions in the valley of Nepal, and within an area of about sixty miles in circumference, upwards of two thousand five hundred species. Twelve months was the space of time devoted to this labor, and it cannot be supposed that he succeeded in discovering all the vegetable productions of that district. From these and other data, it has been calculated by Dr. Wallich that we are not acquainted, at the present moment, with more than the eighth part of the flora of India; an estimate by no means improbable, but which gives to India itself as many species of plants as we find described in botanical works.

No country in the world produces so large a num-

ber of forest trees as India; many of them of the highest value for timber, and, unlike our European trees, often distinguished for ample leaves and large and fragrant flowers. Nothing can be more glorious than the appearance of an Indian scene during the period, or soon after the rainy season, when the whole country is replete with fragrance and verdure; when many of the more delicate herbaceous plants, which had vanished, or languished under the intolerable heat, put forth their blossoms of every hue with astonishing rapidity, and seem by their wild luxuriance to express their joy and gratitude to the great Author of nature. An endless variety of shrubs adorn the hedges, which are often formed of some kind of *Euphorbia* or the odoriferous *Pandanus*, while cucurbitaceous plants, and a vast number of bindweeds and other climbers, interlace their flexible branches, overtop the hedges, and decorate even lofty trees with festoons of living drapery. A species of *Trichocaulis* ascends to the tops of the highest trees, and produces a beautiful white flower with a fringed border, but which, expanding only in the night, is rarely seen; while the abundant fruit, nearly as large as a small orange, and of a vivid scarlet color, is very ornamental. So numerous are climbers of this description, that trees and shrubs are lashed as it were together, and the Indian forests or jungles often rendered impenetrable except to birds and wild animals.—Where the silk cotton-tree (*Bombax ceiba*) and the Decansee-bean (*Butea superba*) abound, the effect which is produced by the crimson blossoms of the one and the scarlet blossoms of the other, has been described as inconceivably splendid.

Captain Raper, in his Survey of the Ganges, when speaking of the vegetation at a great elevation, mentions a species of oak, bearing acorns as large as pigeons' eggs, and of the same form—and abundance of hazel and walnut trees.

Rhododendrons, Andromedas, and Gualtherias have a range from the temperate to the frigid regions.—*Rhododendron arborescens*, the most beautiful species of a beautiful genus, rises along the mountains to the height of a tree, with a trunk of above twenty feet, bearing large clusters of vermillion colored flowers at the ends of the smaller branches. Rose-colored and white varieties were found by Dr. Wallich on the very summit of the mountain Sheopur, in Nepal, at an elevation of ten thousand feet. Even the strawberry flourishes, and the nearly allied genus *Potentilla* furnishes among others two most remarkable species, *P. formosa* and *atrosanguinea*, which, for the sake of their fine red flowers, have been transported from the lofty summits of Nepal to the flower gardens of Europe.

Even *Magnolia insignis* is a tree of vast size, the trunk being frequently four or five feet in diameter. When in full blossom, it is affirmed by its estimable discoverer to be one of the most magnificent objects ever beheld; the large, fragrant, and beautiful yellowish-white flowers are produced in vast numbers amid the dark green foliage, and are succeeded by oblong cones of purple capsules, from which the scarlet seeds are suspended by delicate white threads. This noble tree will bear, there is little doubt, the climate of Great Britain; and to try the experiment, at least, is one of the many laudable objects to which Dr. Wallich looks forward on his return to India.

The principal species made use of in the making of paper, is the *Daphne caroliniana*. It is a very branching shrub, six or eight feet high, with lanceolate shining leaves, and grows in the mountainous parts of Hindostan, from Nepal to the province of Kemaon. The flowers are exquisitely fragrant, resembling those of the *D. odora* of our hot-houses.—The paper manufactured from the bark is of various dimensions and texture. The finest kind measures ten feet in length by four feet in breadth, and is manufactured chiefly in Dotee, a province to the eastward of Kemaon. It approaches in softness and

size to that which is made in China, and Dr. Wallich thinks it is not improbable that some of the latter may be produced from the same material. The following particulars are extracted by Dr. Wallich from the MSS. of Lieutenant H. R. Murray, forming a part of that gentleman's official correspondence with the Military Board at Calcutta:—"The *Set-Burua*, or paper-shrub, is found on the most exposed parts of the mountains, and those the most elevated and covered with snow, throughout the province of Kemaon. In traversing the oak forests between Bheenmah and Ramghur, and again from Abnora to Chumpawat, and down towards the river, it has come under the immediate observation of the writer of these communications, that the *Set-Burua* or paper-plant, only thrives luxuriantly where the oak grows; so that it is not likely that it will succeed in the plains. It is hardy, and attains a height of five or six feet; blossoming in January and February, and opening its acid red fruit about the end of April.—The paper prepared from its bark is particularly calculated for cartridges, being strong, tough, not liable to crack or break, however much bent or folded, proof against being moth-eaten, and not in the least subject to dampness from any change in the weather; besides, if drenched or kept in water for any considerable time, it will not rot. It is invariably used all over Kemaon, and in great request in many parts of the plains, for the purpose of writing *nushbaums*, or genealogical records, deeds, &c. from its extraordinary durability. It is generally made about one yard square, and of three different qualities. The best sort is retailed at the rate of forty sheets for a current rupee, and wholesale at eighty sheets. The worst sort, however, is of a much smaller size, and retailed at a hundred and forty sheets, and wholesale at a hundred and sixty or seventy for the rupee. The following is the very simple process of manufacturing this paper: After scraping off the outer surface of the bark, what remains is boiled in fair water with a small quantity of the ashes of the oak,—a most necessary part of the ingredients,—which has the effect of cleaning and whitening the stuff. After the boiling, it is washed, and immediately beat to a pulp with small mallets on a stone; so that, when mixed up in a vat with the fairest water, it has the appearance of flour and water. It is then spread on molds or frames made of common bamboo mats."

Some of the finest leguminous timber-trees are perhaps to be found in the genus *Dalbergia*. Roxburgh describes *D. latifolia* as one of the largest mountain-trees of the peninsula. The wood is known by the name of *black wood*, and is of a greyish black, with light-colored veins, so heavy as to sink in water, close-grained, and admitting of the highest polish, which renders it highly esteemed for furniture. Dr. Roxburgh mentions having seen planks of it from the Malabar coast full three feet and a half broad; and allowing nine inches of white wood to have been on the outside, the circumference must have been fifteen feet, exclusive of the bark. Equally useful, and possessing the advantage of being one of the quickest growing timber trees in the world, is *Dalbergia cissu*. This wood, we are informed by Dr. Wallich, has no rival for purposes where toughness and elasticity are required to be combined. It does not splinter when penetrated or perforated by a cannon-ball. Throughout Hindostan the naves, felloes, and spokes of gun-carriage wheels are made of it in preference to any other. In the navy it is chiefly excellent for what are called crooked timbers. For all these purposes it attains a sufficient size in thirty-five or forty years: this is proved by several trees which were planted in the botanic garden at Calcutta in the year 1796, and which have now an elevation of eighty to a hundred feet, and a circumference of fourteen feet.

The next plant that we shall notice in our selection of leguminous species is perhaps one of the most interesting. This is the rice paper-plant, (*Eschymene paludosa*), the *Shola* of the Bengalese. Rice-

paper is prepared, or rather simply cut out of the stem of an herbaceous plant, to which Roxburgh gave the name above mentioned. The portions of the stem which we have seen are several inches in length, and from half an inch to above one inch in diameter, and entirely composed, to the very centre, of a fine white cellular tissue, marked in a transverse section with two or three delicate concentric circles, resembling those in the woody structure of dicotyledonous plants. The Chinese dye it of various colors, and employ it chiefly in the manufacture of their artificial flowers. The plant is perennial, of straggling low growth, and seldom exceeds a diameter of two inches and a half in the stem. It is brought to the Calcutta bazaars in great quantities in a green state; and the thickest stems are cut into laminae, from which the natives form artificial flowers and various fancy ornaments to decorate their shrines at Hindu festivals.—The Indians make hats of rice-paper, by cementing together as many leaves as will produce the requisite thickness; in this way any kind of shape may be formed; and when covered with silk or cloth, the hats are strong and inconceivably light. It is an article of great use to fishermen; it forms floats of the best description to their extensive nets. The slender stems of the plant are bundled into fascines about three feet long; and with one of these under his arm does every fisherman go out to his daily occupation.

The mahwah tree, or Indian butter-tree, (*Bassia butyraga*), the oil or illecepi tree, (*Bassia longifolia*), and the shea-tree, or butter-tree of Africa, probably also a species of *Bassia*, are among the number.—The mahwah tree is the most remarkable one in India; it is about the size of an English oak, according to Forbes, but with a beautiful large shining foliage.—The flowers are produced in full clusters at the ends of the smaller branches, and look exactly like berries, the true fruit, however, resembles a walnut, the olive-shaped seeds of which are replete with a thick oil, which is used as a substitute for ghee. The flowers are equally prized, for when dried in the sun they have been compared to Malaga raisins, both in flavor and appearance. They are eaten, in fact, in various ways—as a preserved fruit, as an ingredient in curries and other dishes, or even in their fresh state.—A good tree will produce in one season nearly three hundred weight of flowers. Their greatest consumption, however, is in the distillation of a kind of spirit, which goes by the name of mahwah-arack, and is so cheap that an English pint may be had for one pice, about the value of a halfpenny.

The oil expressed from the fruit of *Bassia longifolia* is constantly used by the common people instead of ghee and coconut oil. The flowers are also collected for food, as in the preceding species, and almost every part of the plant put to some use. It is said that owls, squirrels, lizards, dogs, and jackals eat the flowers, and that the latter sometimes become mad by partaking too freely of them.

Urceola elastica, or the elastic gum-vine, is a plant of this order, which yields a viscid milky juice, possessing the properties of caoutchouc. It is an extensive climber, two hundred yards or more in length, winding among the branches of the loftiest trees, and rising above them into the open air. The milk, when exposed to the atmosphere, becomes solid; and by means of it Mr. Howison succeeded in rendering cloth water-proof, and suggested that it might be applied to the making of hats, great coats, tents, coverings for carriages, &c. The plant grows in Sumatra also, and Dr. Roxburgh believes that the Chinese make their elastic rings from its juice.

GRASS LANDS.—If a supply of fine manure is on hand, scarcely your grass lands, and then give them a topdressing with manure. This will greatly increase the quantity of hay. If you have reason to think moles, ants, and the frost have rendered ground uneven, the grass will be benefited by rolling.

[New York Farmer.]

(From the New York Mirror.)

ARBORICULTURE.

Those of our readers who feel interested in arboriculture, may remember the republication by Messrs. Thorburn & Sons, last year, in this city, from the English edition, of a work entitled the "Planter's Guide."—This was a treatise by Sir Henry Stuart, embracing various information on the subject of removing large trees. However much our countrymen boast of the American forests, the knowledge how to transplant the giant ornaments of the wood, for the embellishment of their dwellings, is by no means uninteresting; on the contrary, all gentlemen owning seats, and not acquainted with the successful experiments accomplished by Sir Henry Stuart, and stated in his book, must be gratified to know that they could overshadow their mansions with large and umbrageous trees, of any size or age, at an expense not exceeding 2 or 3 dollars each.

We have been favored with a letter from a gentleman who called on Sir Henry Stuart, at his residence, Allanton house; a lovely abode, beautified with many practical illustrations of his theory, and who presented him with a copy of the New York edition of his book. We extract a few paragraphs from his communication:

"I rode from Edinburgh, twenty-eight miles on purpose to see Sir Henry, and with book in hand introduced myself into the fine hall of Allanton house. He received my message rather coldly. 'A gentleman from America.' Word came out by the servant that Sir Henry was just going to set out on a journey, but if I wished to see the trees, he would order a person to shew me his grounds. I replied that I wished particularly see himself, and would detain him but a few minutes. Thus summoned he appeared—a neat looking old gentleman, about sixty-five, of rather a spare habit, and both active and intelligent.—On making known the object of my coming, he took me into the drawing room. I told him how happy I felt on being enabled to pay my respects to him, and particularly on a day (it was Washington's birth day) dear to every American. He almost embraced me, declaring that he thought Washington one of the most illustrious of men, and that he was glad that the animosities between the two countries were fast giving place to friendly feeling. He expressed himself proud and surprised that his book should be published in America, the last people, he thought, who would feel any interest in his theory. He observed it had been translated into German and French, but he never dreamed of America—that land of tree extermination without mercy. He examined and re-examined the book, until he grew ecstatic, uttered his astonishment that in America we could get up so beautiful a piece of workmanship; admired the plate, the wood cuts, the paper, &c. produced the Edinburgh copy, declaring the N. York the handsomest in every respect. He then introduced me to his family, showing them the book, and expressing his surprise at its beauty and low price. He immediately deferred his journey, and insisted on showing me over the grounds in *propria persona*. It was a charming sunny day. You would have been delighted to hear his interesting observations on the trees he had removed. They really looked fine, and very vigorous, even to the extreme ends. All those in the park, and many in other parts of the place, with the exception of three or four standard old fellows, were transplanted by the machine. The lake is altogether a work of his own; it is upwards of a mile in circuit, and twenty feet deep, and so planned, that from no point can you see its termination. There is a pretty little island of an acre, which he filled with trees in a week. Does it not seem like fairies' work? The lake abounds with fish; and has an ingenious contrivance under the arches of the bridge to prevent the pike from destroying their less pugnacious neighbors. Noble swans were sailing on the lake, and on desiring Sir H. they fol-

lowed us until he had to stop and feed them with some biscuit, which he carries in his pocket for that purpose. They came up to his hand, and after receiving the expected favor floated away.

"The family would hardly allow me to depart, and wished me to spend a day with them. On my taking leave, Mrs. MacDonald, a daughter of Sir Henry, and her son accompanied me a mile on the road; after which the latter proceeded on with me for fear I should lose my way, as we had a mile or two to walk across the fields and roads to meet the Glasgow mail. Sir Henry is going to write me an account of some improvements in his theory, to be published, or added to the next edition. He informed me that it is now out of print, but a third edition will be shortly published. He recommends a tree of twenty-five feet as the best for the machine; although he asserts that if the machine was large enough, any tree could be removed. Thirteen or fourteen shillings he remarked was the whole expense, and often less."

VEGETABLE NATURE.

Smellie, in his Philosophy of Natural History, has the following remarks on what is called the "sleep of leaves."

The leaves of many plants fold up during the night but, at the approach of the sun they expand with renewed vigor. The common appearances of most vegetables are so changed in the night, that it is difficult to recognize the different kinds, even by the assistance of light.

The modes of folding in of the leaves, or of sleeping are extremely various; but it is worthy of remark, that they all dispose themselves so as to give the best protection to the young stems, flowers, buds or fruit. The leaves of the Tamarind tree contract round the tender fruit, and protect it from nocturnal cold. The Cassia, the Senna and many others, contract their leaves in a similar manner. The leaves of the Chickweed, the Asclepias, the Atriplex, &c. are disposed in opposite pairs. During the night they rise perpendicularly, and join so close at the top that they conceal the flowers. The leaves of other plants are placed alternately. Though horizontal and even depending during the day, at the approach of night they rise, embrace each other, and protect the tender flowers. The leaves of the night shade, are horizontal during the day, but in the night they rise and cover the flowers. The Egyptian Vetch erects its leaves during the night in such a manner that four seem to be one leaf only. The leaves of the White Lupine in the state of sleep hang down, and protect the young buds from being injured by the nocturnal air.

These and similar motions are not peculiar to the leaves of plants. The flowers have also the power of moving. During the night, many of them are enclosed in their calyxes. Some flowers, as those of the German Spurge, Geranium Strictum, and common Whitlow Grass, when asleep hang their mouths towards the earth, to prevent the noxious effects of rain or dew.

The cause of these movements which constitute the sleep of plants, has been ascribed to the presence of the sun's rays. In some of the above mentioned examples the motions produced are evidently excited by heat. But plants kept in a hot house, where an equal degree of heat is preserved both day and night fail not to contract their leaves, or to sleep, in the same manner as when they are exposed to the open air. This fact evinces, that the sleep of plants is rather owing to a peculiar law, than to a quicker or slower motion of the juices.

MANUFACTURAL PLANTS.—Farmers should endeavor to become acquainted with the plants that are used in manufactories, with a view of introducing more or less of them in their routine of culture.—Woad, madder, flax, hemp, mustard, oil plants, rape, poppy, rhubarb, and numerous others, are used in the arts, domestic economy, and medicine.—N. F. Far.

A GUIDE TO ORCHARDISTS.—Mr. Michael Floy, well known as a florist and nurseryman of this city, has just published Mr. Lindley's celebrated work with the above title, with additions, notes, and corrections. We have not had time to read the work, but have no reluctance, from Mr. Floy's experience, and accurate knowledge, to recommend the work as one, the merits of which will render it a standard.—The work is closely printed, and contains more matter than the English edition, with half the price.

[New York Farmer.]

RURAL ECONOMY.

CULTURE OF BEES.

MR. SMITH: *Henrico, Va. May 3, 1833.*

For many years I have paid much attention to the raising and management of bees; and before the miller or moth worm made its appearance, about eighteen years since, I had been very successful. The quantity of honey produced was much greater when I used the double hives, and after I had declined driving and robbing them, which I seldom did with success. But since the appearance of that destructive fly or worm called, by some, the miller, I have scarcely made honey sufficient for family purposes. I was much pleased to see in your paper, of March 29th, an extract from the Genesee Farmer, of the experiments made by W. W. B., who appears to have thought much upon the subject, and to be anxious to discover some method of stopping the ravages of the worm. I have tried many ways, and have not yet succeeded. First, I made a good shelter, of sufficient size to cover eighteen or twenty, with a large thick bench to set them on. Both ends of the hive were made perfectly tight, and holes made about an inch from the bottom, for ingress and egress. This not effecting the desired object, I had spouts inserted into the side of a hive, for them to pass in and out. Others I have placed upon pivots or little pebbles, and sometimes have placed one or two on the ground. Some few years since, having a cavity in the side of my house, about eight feet high and twelve inches square, I concluded to use it as a beehive; and accordingly made a hive with two apartments. (two doors to each apartment;) one of glass, the other of wood, to darken the hive. Into the lower apartment I put a swarm of bees, through the lower sash of the inward door, and inserted a tube, of one inch diameter and six in length, through the wall of the house as a place of ingress and egress. They appeared to do very well for a while, when I discovered the fly had got in and observed a little of the web on the exterior of the comb. Some time after this, I killed them, and took about five gallons of honey. I have since put in a new hive, made very tight; and about this time two years since, I ushered in a new swarm as before—hoping, from the size of the lower and upper cavity, they would remain there until they had filled both, without swarming. But to my astonishment, believing they would never swarm so long as they had room sufficient, about June last there came out a very large swarm. I have seen through the glass one of those flies that deposite the egg, from which the worm comes, running about inside of the hive, as if looking for some way of retreat. I have not discovered, however, any injury as yet from them in this hive. But if it be true, as an old bee hunter of veracity has told me, that bees found in trees twenty-five feet from the ground were injured, I fear neither the plan of W. W. B. nor mine will avail. I am now trying the following plans to keep out the worm. 1. I have fixed my bee house in such a manner as to enable me to suspend all my hives about six inches above the bench, by hanging them upon a hook, or fixing them on two pieces extending from one end of the house to the other. 2. I have had a hive made twelve inches square and fourteen inches from the top to the shoulder; the sides sawed in, and with the use

of hot water, bent and brought to a point, just so close as to be sufficient to admit the passage of the bees. This I have suspended about a half an inch from the bench, leaving no place for a deposit. I have not had a trial sufficient to ascertain the utility of this method; but if suspending is best to keep out the worm, I am satisfied it is best to have them made in this way for the following reasons:—1. The hive swings better upon the rack spoken of above. 2. The jaws of the hive being brought to a point, leave no place for a deposit of that farinaceous substance which is so often found at the bottom of bee hives, and which is so congenial to the hatching of the worm. Besides, the bees find much less difficulty in entering a suspended hive made in this way, than in the hive which is open at the bottom the full size.

R. H. S.

(From the Western Pioneer.)

RECEIPT TO CURE HAMS.

The following receipt has been communicated to us for publication. We are assured that the result of the process recommended will render the pork of a delicious flavor; so much so as to cause the most stubborn Jew in Christendom to forswear the religion of his fathers:—aye, even choice enough to lure the shade of departed Epicurus for the richest banquet of an Elysian paradise.

To cure a dozen hams of ordinary size and weight, take twelve pounds of common packing salt, one pound of saltpetre and one gallon of molasses: rub the hams thoroughly with this composition, and pack them down as closely as possible in a cask. Let them remain one week; then take one-half a bushel of hickory ashes, make of it a strong ley, add to it a pickle which will bear an egg, pour the pickle so as fully to cover them, and let them remain in it three weeks.

In the summer season, after the hams are smoked, put them in a cask in layers, with layers of perfectly dried tan bark between them.

RECEIPT FOR MAKING TOMATO SAUCE.

Take tomatoes when ripe, and bake them till they become quite soft; then scoop them out with a teaspoon and rub the pulp through a sieve. To the pulp put as much Chili vinegar as will bring it to a proper thickness, with salt to your taste. Add to every quart half an ounce of garlic and one ounce of shallots, both sliced very thin. Boil it one quarter of an hour; then strain and take out the garlic and shallots. After standing till quite cold, put the sauce into stone bottles, and let it stand a few days before it is corked up. If, when the bottles are open, the sauce should appear to be in a fermenting state, put some more salt, and boil it over again. The sauce should be the thickness of rich cream when poured out, and is, in my opinion, far superior to the famed Bengal chutney, to which it bears considerable resemblance.—*B. B. Sept. 6, 1831.*

(From the Saturday Evening Post.)

FEEDING SWINE.

Sir,—You will oblige an old subscriber, and perhaps benefit the public, by inserting the following:

I observed in your paper, of the 19th of the last month, an article on the feeding of swine, in which was recommended the practice of keeping them constantly penned up. Now, I consider this the very reverse of what ought to be done, for the following obvious reasons: viz.—It deprives the animal from enjoying that perfect state of health, which he otherwise would enjoy, if allowed to range at large; and being constantly fed on greasy dish water, and other impure substances, the meat of course have a strong taste, and lose much of its flavor—and hence we see the reason why the citizens always prefer the country pork to

that of the butchers, who keep their swine constantly in pens, and feed them on filthy animal substances.

The food of swine should be entirely vegetable, and when allowed his liberty will feed considerably on grass, acorns, chestnuts, apples, cherries, &c., which he is entirely deprived of in a state of confinement. It is true he will fatten much faster, when confined, than when running at large. Just so it is with a human being when confined to his chamber—if not absolutely sick, he will grow fat and fleshy; but it will not be solid, nor will he enjoy as much health and spirit as when he takes daily exercise in the open air. And this is the case, without exception, with all the animal creation; and even the vegetables require the force of the sunshine, wind, and rain, to make them thrive.

The milk of the cow, in a state of confinement, is not fit for use. This I know by experience—for being accustomed to use milk, instead of tea and coffee, and boarding at a tavern in this city, where the cow was kept constantly in the stable all the year, the milk, particularly in the summer, had such a disagreeable sickening taste that I could not possibly relish it. For the same reason also, the flesh of wild fowls and animals is much sweeter, and has a finer flavor, than those kept in confinement, because they have free exercise in the open air, drink the pure crystal stream, and live on that kind of food, which nature intended.

But, to conclude, I would observe, that all those who live on small lots, and have no range for swine, are generally obliged to keep them in pens, if they keep them at all; but all farmers, who have a convenience to let them run at large, should embrace the privilege, if they wish their pork sweet and good.

But in the autumn previous to their being killed, it is customary, and no doubt very proper, to pen them up a short time, in order that they may fatten the sooner; but during which period, corn should form the principal article of food. Yours, &c.

A FRIEND TO DOMESTIC ECONOMY.

MISCELLANEOUS.

BRAN OR HULL OF WHEAT, &c.

In a French paper, we find the following extract from the proceedings of the Academy of Sciences, which we translate for the benefit of our readers:

Economical researches relative to the bran or hull of wheat and other bread stuffs, by Dr. Herpin. The author gives the results of his researches in the following propositions:

1st.—That the envelope or cortical part of the wheat forms at least one-twentieth of the weight of the grain.

2dly.—That nevertheless by the customary mode of grinding, wheat produces one-fourth of its weight in bran.

3dly.—That about seventy-five per centum of the nutritive substance of the grain is left in the bran.

4thly.—That by simple washing, there may be drawn from the bran one half its weight of the first quality of flour or oatmeal, according to the nature of the grain.

5thly.—That there may, by this mode of proceeding, be made from grain at least fifteen per centum, more bread than is at present obtained; that is, from the same quantity of grain now used in France, there might be had three millions of kilograms of bread per day, more than is now obtained.

(From the New Hampshire Sentinel.)

EXTRAORDINARY BULL.

The man who raised the best stock of cattle, heretofore, or any extraordinary animal, has received not only honor but a premium. Mr. Henry Wheeler, of Nelson, has beat them all. He killed a bull only fourteen months old on the 5th

March, which, on being dressed, was found, to the surprise of the beholders, to have hoarded up the substantial which made him the most valuable animal of his size ever raised in America! Bank bills in good order and well conditioned,—not a counterfeit among them,—were taken from the animal, to the amount of sixty-one dollars. The owner challenges competition.

A solution of the above—One day last week, Mr. Sam'l Derby of Nelson, in the act of taking out a string from his pocket to measure a pair of cattle he was about to purchase, pulled out his pocket book unconsciously, containing sixty one dollars in bank bills. The pocket book was soon after seized by a yearling bull, and before it could be extricated was pretty well masticated and swallowed. The bull was immediately killed and all the money taken from the stomach of the animal uninjured.

(From the Medical Journal.)

A CHEAP AND CONVENIENT BATH.

There is one mode of refreshing and hardening the body that is extremely cheap, extremely convenient, and yet seldom adopted. The warm and cold water bath is indispensable to health. No system can go on with its full natural vigor so long as the pores of the skin are encumbered and obstructed by the particles of perspirable matter, that, not being carried off by evaporations, accumulate on the surface. In some form or other, general ablution is required, and that often, by all animals, and by none more than by man. Independently of the benefits of cleanliness derived from such baths, there are other advantages resulting from them, which it is not our purpose here to discuss; and which, to medical men certainly, are already sufficiently familiar. But the cold and the warm bath are attended with some inconvenience, and with some expenditure of time, and, in this city, of money also. It is not an indifferent matter, therefore, that all should be reminded of the power of the air bath, in promoting both health and comfort, and rendering the water bath less frequently necessary. It costs nothing to expose one's self a few minutes, on rising in the morning, to the air of a dressing room; and, after a short time, it will always be regarded as luxury. In summer, the windows of the apartment may be open, and the external air admitted freely around the person. If to this delicious and invigorating bath, friction be added, we can scarcely name a more sure method of preventing disease and imparting tone and vigor to the whole system.

Time even need not be given to this bath. The windows being thrown open, and the door of the dressing room shut, the operation of shaving (which, by the way, is performed at this time with more ease, and less danger of drawing blood, than at any other part of the day) and the ceremonies of ablution may all be performed in a state of nudity; so that the most thorough air bath may be taken every day, without the least possible expense, even of a moment's time, without inconvenience, and with great advantage to the body and the mind.

We forbear to dilate on this subject. To the wise, the words already written will be sufficient. The foolish, pages of argument and explanation would but confirm in their folly.

ENGLISH PARTIALITY FOR FLOWERS.—The nation altogether has a particular love for trees and flowers. The lord has in his parks, oaks of a thousand years' growth, untouched by the axe, hot-houses full of exotic plants, exquisite fruits and the rarest flowers; there is not a cottage in England which has not before it a little piece of ground for the cultivation of flowers, and even the poor town imprisoned artisan works at his loom in sight of a pot of flowers, placed on the window sill, (with a mind no less generous than my lord's,) in order that the passengers also may enjoy the sight of them.—*Italian Exile in England.*

PUBLIC SALE OF DURHAM SHORTHORNED CATTLE AND HIGHLY IMPROVED SHEEP.

Will be sold on Wednesday, 29th day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd, the highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEIFERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand.

DAVID MEADE, Administrator.

April 5,—81

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale.

Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life,) is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also,—A young JACK, a son of Don Carlos, 4 years old, 13 inches high, well made, stout and promising, of same color as his sire—price \$200.

Also,—A full sister of the last, 3 years old, 44 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at 75 cents per bushel.

I. I. HITCHCOCK,

American Farmer Office and Seed Store.

200,000 WHITE MULBERRY TREES.

The Subscriber has on hand and for sale 200,000 White Mulberry Trees of two and three years' growth, which have been transplanted, are in a healthy and thrifty condition, and which he offers for sale at \$1.50 and \$2.00 per hundred, delivered at the nursery.

Also, a few of the *Morus Multicaulis*, or Chinese White Mulberry.

ASA BUTLER,
Suffield, Connecticut.

P. S. All orders (post paid) will be punctually attended to. April 12,—61.

SINCLAIR AND MOORE'S NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Bushes, (among which is the much admired Greville,) double Altheas, Honeysuckles, Cornus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Alanthus, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees, Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets. Feb. 22.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Scythes, Grain Cradles, Scythes, the Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Coneave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—Some alterations will be noticed in the prices of produce. Flour has advanced, and a tolerably fair business is doing; the same remarks apply to all kinds of grain. City mills flour has advanced above Howard street, in consequence of there being greater certainty of freshness, which is all important at this season, particularly when the flour is for exportation.

Tobacco.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 769 lbs. Md.; 106 lbs. Ohio; and 1 hhd. Vir.—total 576 lbs.

Flour—best white wheat family \$6.75 a 7.25; super Howard-street, 5.37½ a 5.50; city mills, 5.50 a 5.75; city mills extra 5.50 a 5.75.—Corn Meal bbl 3 62½.—Grain, best red wheat, 1.20 a 1.25; white do. 1.30 a 1.35; —Corn, white 65 a 66, yellow, 66 a 67;—Rye, 75 a 77 —Oats, 37½ a 41.—Beans, 75 a 80.—Peas, 65 a 70.—CLOVER-SEED, 8.00 a —.—TIMOTHY, — a —.—ORANGE GRASS, 3.00 a —.—Tall Meadow Oat Grass 2.00 a 2.50.—Herd's, — a —.—Lucerne — a 37½ lb.—BARLEY.—Flanders 1.50 a 1.62.—Cotton, Va. 10 a 12.—Lou. 12 a 13.—Mah. 12 a 13.—Tenn. 10 a 12; N. Unwashed, Prime or Saxony Fleeces, 25 a 30; American Full Blood, 22 a 25; three quarters do. 20 a 22; half do. 18 a 20; quarter do. 16 a 18; common, 16 a 18. HEMP, Russia, ton, \$195 a 205; Country, dew-rotted, 6 a 7e 1b. water-rotted, 7 a 8e.—Feathers, 36½ a 37½.—Plaster Paris, per ton, 5 25 a 5 50. Ground, 1.50 a — bbl. Iron, gray pig for foundries per ton 33.00 a —; high pig for forges, per ton 28.00 a 30.00; bar Sus. per ton, 75.00 a 85.00.—Prime Beef on the hoof, 5.50 a 6 25.—Oak wood, 3 00 a 3 25; Hickory, 4 50 a 5.00; Pine, 2, 25.

CONTENTS OF THIS NUMBER.

Editorial: The Drought—Letter from Commodore Porter to John S. Skinner, Esq. enclosing some of the Seed of the Oriental Cypress Tree—Barney's Bake-well Sheep—Rural Labor beneficial to Professional Men—Cobbett's Cottage Economy; Mustard—Prospect of the Wheat Crop—How to Sow on Glazed Calico—An Address delivered before the Worcester Agricultural Society, October 10, 1832, by Waldo Flint, Esq.—Extracts from the Historical and Descriptive Account of British India—Grass Lands—Arboriculture; Sir Henry Stenart's Residence—Vegetable Nature; Sleep of Leaves—Manufactural Plants—Lindley's Guide to Orchardists—Experiments on the Culture of Bees with a view to prevent the Ravages of the Bee-moth—Receipt to Cure Hams—To make Tomato Sauce—On Feeding Swine—Bran of Wheat, &c.—Extraordinary Bull—Cheap and Convenient Bath—English Partiality for Flowers—Prices Current of Country Produce in the New York and Baltimore Markets—Advertisements.

GENERAL

Agricultural and Horticultural Establishment: COMPRISING,

A Seed and Implement Store, a General Agricultural Agency, and the Office of the AMERICAN FARMER, at No. 16 South Calvert street, Baltimore; in connexion with a Stock and Experimental Farm, Garden and Nursery in the vicinity.

§ An extra number of the Farmer, containing a prospectus of the "Establishment," and a "Catalogue of Seeds," &c. kept for sale, shall be sent GRATIS to any person who shall by mail or otherwise furnish his address for that purpose.

AGENTS FOR THE FARMER.—All postmasters are requested to act as agents for the Farmer, and to require a strict compliance by subscribers with the terms, especially the third item. They are authorised to retain one dollar for each new subscriber, and ten per cent on all other collections. The list of special agents is published in the Farmer every third week. (Terms next week.)

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, MAY 17, 1833.

THE SEASON—DALILIAS.—The drought mentioned in our last as being very severe, was happily quenched on the very day our notice of it was published.—On Friday, a change took place in the weather: we had a steady light rain till Sunday morning, and “spring showers” occasionally, to the present time. This change afforded a good “season” for transplanting, and we doubt not, it was generally availed of by gardeners and planters. The editor of the Farmer, at least, took advantage of it, for transferring to the open ground, one of the largest collections of dalilias ever seen in America, consisting of about two thousand plants, fifteen hundred of which are *new*, and the others the most celebrated kinds. The lovers of flowers will hear more of this collection in the fall.

The following paragraphs will give an idea of the season, in the various sections of the country whence they emanate:

Extract of a letter from a subscriber, dated

“McDonnough, Henry Co. Geo. April 28, 1833.

“Our spring is very late, attended with cold, and generally very wet weather. Our grapevines have been retarded in their vegetation so long, by the coldness of the season, that the frosts have had no effect upon them thus far—and now we apprehend no danger from that source. The prospects, at present, are favorable for an abundant crop of grapes.”

Extract of a letter, dated,

“Cleveland, Ohio, May 4, 1833.

“Such a drought, I never before experienced in this country, at this season of the year. Our small grain is turning yellow, and must soon perish for want of rain, and it is useless to plant Indian corn, unless you want to kiln-dry it. Give me a brush of a hurricane now and then, rather than a spring drought.

Yours, respectfully, J. C. S.”

THE COMPASS PLANT.

MR. SMITH:

Cleveland, Ohio, May 4th, 1833.

In the first number of your current volume, is an account of the *compass plant*. Upon reading the article, I thought it probably might be a *Silphium*—perhaps, the *S. gummiiferum*, “almost exclusively a prairie plant,” or the *S. terebinthinaceum*. (See Elliott’s Botany, vol. ii. pp. 460 and 463.) The other name of the plant your correspondent speaks of, (*rosin weed*.) appears to agree with both the specific names of Elliott, though I can find nothing said with regard to the polarity of its leaves, which certainly is a very remarkable and striking feature. I think I have heard some such quality attributed to the leaves of Indian corn, and if I do not mistake, mention is made of the same in some of the volumes of the American Farmer. I have not time, at present, to hunt up the article.

Some time last fall, I received from a friend, who got them from Arkansas, a few seeds, which were given to him as those of the *torpentine plant*. The following memorandum accompanied the package, made by the gentleman who gathered the seed in Arkansas:—“This is the seed of a plant unknown to me—it grows six feet high, and looks very majestic—yields a *pitch* or *rosin*, somewhat like *torpentine*, about the stock. It has a pretty large root: the size of a parsnip or the Columbo-root, and tastes like some medicine I have taken. It is undoubtedly some valuable medical plant.” I think upon comparison you will say this Arkansas vegetable, and the one described by Mr. Speed, as coming from Missouri, are one and the same—and very probably one of the *Silphiums* above mentioned. This we cannot tell, however, until we get the flower. Not having any mode of

forwarding to you a larger quantity, I herewith send you two seeds of the *torpentine plant* I got from Arkansas—I think you will find, if they vegetate, that they are identical with those you received from Missouri. I also send you a couple of seeds, gathered by myself, on the banks of the Ohio, from the *Silphium perfoliatum*. You see how similar they are to the Arkansas seeds. The *S. perfoliatum*, is well worth a place in a botanical garden. It grows nearly ten feet high in our luxuriant bottom land, and has a majestic and civilized appearance, as it were, demanding homage from the rough weeds that surround it.—Should you plant these seeds, place them in the richest and moistest ground you have.

I obtained at the same time, and by the same hand, some seed of the “Arkansas wild cabbage,” which may afford, at some future day, a subject for another communication.

Can you not raise a subscription in Baltimore, to collect the necessary funds, to forward to Commodore Porter, for the purpose of obtaining the Angora goats? Yours, very respectfully, J. C. S.

[We agree with J. C. S. that the “Compass plant” is most probably a *Silphium*. The seed sent us by Mr. Speed, did not vegetate.—Ed. Am. Far.]

(From the New England Farmer.)

WASH FOR FRUIT TREES.

Although we have heretofore published the following, we again insert it for the benefit of young farmers and recent subscribers. It was recommended by Mr. Benjamin Wheeler, of Framingham, Mass., and first published, we believe, in the New England Farmer, vol. iv. p. 213.

“Dissolve two pounds of potash, of the first quality, in seven quarts of water, for the bodies of the trees. If the limbs are covered with moss or lice, I take a painter’s brush, and apply the solution to the moss, &c. with care not to touch the leaves or buds. It may be done at any time of the year when we are most at leisure. Once in two to four years is generally sufficient. I have no general rule, however, but wash them as often as they appear to need it, which is always when the bark is not smooth.”

Mr. Wheeler observes, that “No person need be afraid of this application injuring fruit trees; but it may be applied with the utmost confidence. I have used it for nearly twenty years with great effect. I have recommended it to a great many gentlemen, but only a few have used it. Those who have tried it are much pleased with its operation. The reason that it has not been more generally used is, that it has been fashionable to daub the trees with lime, clay, manure, and other compositions, which take two or three years to wash off before the tree will look natural. When this solution of potash is applied, it has the desired effect immediately. It kills the moss and lice at once; and the first rain that comes washes the bark perfectly smooth, and gives it a fair, natural, healthy color.”

It is said that this application was introduced by the late Governor Brooks, in Medford, Mass., the summer before his decease, who believed that it not only accelerated the growth of the trees, but was an *effectual preservative against the borer*. It was applied by that gentleman once every year, either the latter part of May, or the beginning of June. The opinion that the above described wash is a remedy against the borer, is corroborated by Messrs. Winships, proprietors of an extensive nursery, &c. at Brighton. In a letter to the editor of N. E. F. they observe: “Five years ago (preceding 1830) we were exceedingly troubled, having, at the same time, several thousand trees infested with borers. We applied the wash, as recommended by B. Wheeler, Esq. of Framingham, and have continued it ever since, (the first week in June in pleasant weather,) on from five to ten thousand trees, annually. The ad-

mirable effect has been astonishing; not only effectually preventing the destructive effects of the borer, but killing immediately the moss, and destroying those other insects usually found impeding the good health of the tree; also resuscitating and invigorating every kind of tree we have applied it to. We would recommend, as a general wash, one pound of potash to six pints of water. And for promptness of execution the mariner’s long handled tar brush, or the common paint brush will answer. Every other year will answer as a remedy against the borer, although the horticulturist will find himself richly rewarded by a more frequent application.”

LOCUST.—We took the liberty some time since, of inviting the attention of our patrons to the necessity and advantages of growing timber trees; and particularly the locust, because it is easily propagated, the wood is of exceeding durability, and its growth is astonishingly rapid. Cobbett, in his “Woodlands,” furnishes a number of cases showing the rapid growth of the locust, some of which are so remarkable as almost to create doubts of their correctness, in the minds of those who have not attended to this matter.

His first class of cases embrace trees of seventeen years’ growth, the largest of which was *five feet eight inches* in circumference at the ground; the second, trees of 14 years’ growth, the largest of which was *two feet four inches* at the ground; the third, trees of 11 years’ growth, the largest of which, as above, was *three feet two inches*.

After making these statements, Mr. Cobbett adds, did any one of my readers ever know or hear of a growth of timber tree equal to this? Yea, verily, Mr. Cobbett! Ohio has beaten you. To show this we give the size of two locust trees grown in the vicinity of this place, and which may be seen and measured by any person having the curiosity to do so, on the farm of Mr. Aldridge.

The first is of *thirteen years’* growth, and a few days since, measured one foot from the ground, *five feet seven and a half inches* around, and is about the same size, or very nearly so, to where it branches off from the main trunk.

The second was planted in 1828, and has been growing of course five years; it measures *two feet four and a fourth inches*, as above, and is tall, and well formed. He that shall beat this need not despair of growing *Jonah’s gourds*.—Farmer’s Chronicle.

USEFUL IMPROVEMENT.

A patent has been procured at Paris, a gold medal granted, and other honorary distinctions conferred, for the discovery and practice, on a large scale, of preparing from potatoes a fine flour or sago, equal to ground rice, and a *semolina* or paste, of which one pound is equal to one and a half pound of rice, one pound and three quarters of vermicelli, or as it is asserted, to eight pounds raw potatoes. Large engagements have been made for the French marine, and for the military and general hospitals, where it is found serviceable as a nutritious aid with wheaten flour, for biscuits, pastry, soups, gruel and pava.—Count de Chabrol states that 40,000 tons of potatoes are annually manufactured into flour, in a circle of eight leagues round Paris. The manner of preparation is not known. But Mr. M’Innes states, in the Quarterly Journal of Agriculture, his method of preparing tapioca, which is presumed to be somewhat similar to the French mode. The potatoes are grated into water, and the mass is passed through different strainers and waters, until it is perfectly purified from the fibrous matter, and the starch becomes pure and clean. It is then exposed to dry, after which it is dried over a heat of the temperature of one hundred and fifty degrees, and made into cakes till needed for use. It is used in bread, puddings, &c. generally with a portion of wheaten flour. See *Qr. Jour. Ag.* vol. 11, p. 68.

AGRICULTURE.

(From the Southern Agriculturist.)

ACCOUNT OF AN AGRICULTURAL EXCURSION,
Made into the South of Georgia, in the winter of 1832.

BY THE EDITOR.

(Continued from page 19.)

The island of "St. Simons," is remarkable for its healthiness, and the planters enjoy the great advantage of living constantly on their plantations, and superintending in person all of the operations. The character of the soil we have already stated to be, a light sand, and there is a greater uniformity on this island than we have noticed on any other. It is throughout extremely level, neither broken into hills and dales nor intersected by swamps—in fact, there is, we believe, but one on the whole island, and that being at the head of a large creek, can easily be drained. The plantations, with one or two exceptions, are situated on the outer edges of the island, leaving the interior unoccupied, except by a growth of shrubs and scattering wood. This part which, no doubt, at one time was thickly wooded, has been so cleared, that there remains on a large portion but little else than shrubs and trees of a second growth, and unless care be taken in time to guard against the evil, the day cannot be far distant when the want of firewood will be sensibly felt.

We have already noticed the culture of cotton on two plantations; the general mode does not differ materially. Beds are made at the distance of five feet apart, large and flat, occupying nearly the whole of that space. The seeds are scattered over the tops of the beds, and the plants when thinned out are left at irregular distances; varying from eight to twelve inches, not in a line as is common with us, but occupying a width of from twelve to fourteen inches. The plough is in general use, the fields are hoed over from six to eight times in the season; care being taken in the two last hoeings to confine the operations to weeding, rather than to stirring or drawing up the soil, both of which are believed to occasion a dropping of the pods and forns. In one of Mr. Couper's fields, we saw some very luxuriant plants; but the height of what we saw in most of the fields, would not, we think, average more than four feet. We saw much which was below this. Except on a few plantations, very little labor has been expended in the manuring of cotton, and we saw several fields which were evidently exhausted by the system pursued. The product per acre, varies from one hundred to two hundred pounds, but even this quantity is exceeded on some plantations in favorable years, and the average product of the whole island for 1832, was estimated at two hundred pounds.

The cotton on most of the plantations, if not all, is got out by Eave's gins, propelled by animal power. The quantity ginned per diem, is certainly considerable, and our planters would do well to ascertain whether they might not be advantageously introduced into this State. We are aware that they have been tried and abandoned, owing, in all of the instances which we have heard of, to a difficulty in managing them. We are somewhat at a loss to conjecture in what this consisted, we saw several at work both on St. Simon's and on the Main, and there appeared nothing likely to occur, but what might soon be remedied by a common carpenter. It is, however, a fact, that they have been several times tried and abandoned on our sea-islands; and yet, in the lower part of Georgia, they are in common use and do gin a large quantity per day, as the statements furnished us, and which we give below, fully prove. We could give but an imperfect idea of the machine by a drawing, certainly not such an one as would enable a planter to have one constructed. We, therefore, content ourselves with merely stating that, according to Eave's original arrangement, the gin consists of two pair of rollers, about thirty inches in length, (we state this from me-

mory, not having measured them,) placed obliquely one above the other. Each roller is confined to its place by several iron boxes placed at regular distances on wooden pieces corresponding in length to the rollers. Below each set are a number of curved wire teeth, five or six inches long, which serve to hold the cotton when thrown in, whilst at the same time the seeds are permitted to escape between them. Another piece of wood having also a number of wire teeth, nearly of the same length is fixed immediately in front of the rollers, and this piece is made so to move by means of a crank, that its teeth pass between those below, and within a half inch of the rollers, taking the cotton at the same time and presenting it to them, and as there is a constant motion upwards and downwards, the cotton is generally in such a state as not to choke the rollers.

These double gins have been found to be somewhat complicated, and recently gins with single sets of rollers have been made, which are found to be much more simple, and to gin more in proportion than the double ones. All are propelled by animal power, and the cog-wheel and pinion driving a band-wheel, are used on all the places we visited. In the arrangement we saw nothing different from that in common use in this state, where animal power is used. The following notes, furnished us by J. H. Couper, Esq. will, however, convey much useful information, both as to the mode of applying the power, and the proportions necessary for each part.

"The simplest and most common plan is to erect a gallows frame of three or four strong posts, connected at top by two large cross beams, that receive at their intersection the upper gudgeon of the king-post. Arms, as usual, are attached to the king-post, and four or five feet above them, in the place of the wheel, twelve or sixteen light arms are substituted, the ends of which are notched to receive a rope or a band of twisted cow-hide.

"The rope or band drives a drum-wheel on the same shaft with the band-wheels that drive the roller pulleys. The drum, band wheels and gin, are contained in a small building adjoining the horse-walk. This arrangement has nothing to recommend it, except its original cheapness and its simplicity. The exposure to the weather occasions a rapid decay in the king-post and frame, and the rope or band requires frequent renewal.

"When the plantation is extensive and two gins are required, it has been deemed advantageous to erect a building thirty-four to thirty-six feet square, two stories high. The first story is occupied by the horse-walk; in the second are the gins and moting tables, and in the third or garret the fan or whipper, with a shop for turning rollers, &c. This arrangement is undoubtedly the most complete and durable; but the expense, forms an objection to its adoption except on extensive plantations. On this plan are the gin houses at Carmen's point, Hamilton, estate of Butler, Dr. Tunno's, and at this place.

"A medium system is that, when the horse-walk is contained in a cheap building, and the gins and other machinery in a small one adjoining. The building to contain the horse walk is made by placing lightwood or oak posts in the ground, with an inclination inwards, to counteract the outward pressure of the rafters. The rafters are secured to the tops of the posts by mortices and tenons, and are suited in the same way to a centre-post. Two strong beams, at right angles to each other, are let down on the heads of two of the posts; they serve to brace the shed and receive the gudgeon of the king-post. The double roller gin has two pair of rollers, and is Eave's original arrangement. Within a few years, Mr. Pottle, of St. Mary's, in this state, has substituted two single roller gins for the double one. He places them back to back, forming an angle with each other, and both are driven by the same band wheels, which are placed above and between them.

"The arrangement is simple and cheap; and four

rollers or two pair on this plan, gin out more cotton than the same number in the double gin, when they are placed over each other, in consequence of the seed from the upper pair falling between the cotton and rollers of the lower, and preventing the cotton being seized by the rollers. Mr. Pottle's gins are very highly esteemed and are much used. He has great practical skill; and is very moderate in his prices. He is in the practice of furnishing the propelling machinery, on the most simple plan, and attends to the erection of the whole. Neither his machinery nor workmanship, are of the best kind, as he studies cheapness and simplicity; but on the whole he may be recommended to your correspondents.

"The proportions of the various wheels admit of a great variety of modifications. The essential points are to gin from six hundred to eight hundred revolutions of the rollers per minute, one hundred and twenty-five strokes of the feeding arm, and from twenty-five to thirty revolutions of the fan in the same time. My brother has gone as high as eight hundred revolutions; our velocity here is six hundred. I am about increasing it to eight hundred.

"A double roller gin, with six hundred revolutions, average thirty bushels of seed, or six hundred pounds of clean cotton per day. I have averaged seven hundred and twenty pounds for twenty-two consecutive days. I obtained one day, nine hundred pounds. My brother averages from four hundred to five hundred pounds per day with a single roller gin, having eight hundred revolutions per minute.

"I can recommend Mr. Ball, of New-Haven, Connecticut, to such, as the maker of the best single roller gins that I have seen. The power required to drive one double gin and fan, will be from two to three good horses. With the gin alone, two horses will be sufficient. The hands required will be, boys to drive the horses, a feeder for each gin, a hand at the scaffold, a girl to bring and take away the cotton, and a girl for the fan or whipper. The occasional attendance of a carpenter to make rollers is also necessary. Total, three boys and three girls, all one-quarter hands, and one full hand, equal to two and a half full workers to six hundred pounds of clean cotton.

"When the cotton of the estate of Butler was separately quoted as a superior article, it was ginned entirely by Eave's gin, as were generally the cottons of St. Simon's.

"This gin has been in use on St. Simon's Island for nearly forty years, and is now in very common use in this and the adjoining counties."

The following proportions for the several wheels have been found most effective. They are also furnished by Mr. Couper.

Bevel-wheel 11 feet diameter and 240 cogs. To the king post, of which are fixed arms for attaching the horses; the point of attachment to be 15 feet from the centre of the king-post.

Bevel-pinion 34 cogs.

Spur-wheel 8½ feet diameter and 108 cogs.

Spur-pinion 1 foot in diameter and 13 cogs.

Band-wheel, driving pulleys on the rollers, 3 feet diameter.

Pulleys 5½ inches, on rollers of from 6-8 to 7-8 inches diameter.

Band-wheel, which drives the wheel to which the crank is attached, 24 inches diameter.

Band-wheel, to the shaft of which the crank is fixed, 26 inches diameter.

The band-wheel which drives the pulley of the fan or whipper, 2 feet diameter; the pulley 1 foot diameter.

Having these proportions, the velocities will be as follows:—the rollers will revolve 383 1/3 times for each revolution of the large cog-wheel. The feeding arms will strike 621 times, and the fan arms revolve 14 times. If the horses go twice around per minute, these velocities will be 766 2/3, 125 and 28, which are the proportions to be observed.

At Mr. Gould's on the south end of the island, we saw one of these gins worked by means of the wind,

and by which he got out the whole of his crop. For this purpose he erected a light circular building, fourteen feet diameter at the base, and twelve feet at the top—the height sixteen feet. The whole made of light scantling, shingled from the bottom to the top, and so constructed as to move on a pivot, and be turned around by a lever so as to face any quarter the wind blows from. Near the top an axle is fixed which projects beyond the building on one side, and has the arms attached thereto: these are placed at an angle of twenty-two degrees, and are fourteen feet long; the sails are made of oznaburghs, using four breadths to each sail. To the axle within the house, is fixed a large band wheel ten feet diameter, from which a band proceeds to the whirl fixed on the gin, which sets the whole in motion. The whole building with its fixtures is extremely light. It is true, that it is not always it can be worked, as the winds are the propelling power, but there is no great loss sustained by this, as a boy alone attends to it, spreading the sails, bringing the cotton, ginning and carrying it away. When the wind blows fresh another boy is sent to assist in bringing and removing the cotton. When in operation a bag is ginned in nine hours.

Corn and potatoes are not productive on this island, owing, it is supposed, to the dryness of the seasons and lightness of the soil. We think, however, that this might be greatly remedied by the application of marsh-mud and marsh-grass to the fields. Both of these have been found highly beneficial to such crops, not only on our islands, but also on the main. We know of no manure which causes a greater production of potatoes than marsh cut green, and carried to the cowpen, from whence it is to be removed after it has been well trampled and mixed by the cattle, and become partly decomposed. That it is not the manure obtained from the cattle which causes this effect, will be made evident to any one disposed to test it, by manuring a small spot with green marsh after it has served as a litter for cattle, and another spot, with what is usually employed in the cowpen. It will be found that the first is much the most productive. The marsh may be used without being carried into the cowpens at all, it will not prove as efficacious, but still will be very excellent. It should, however, if possible, be in a partly decomposed state, which is effected by keeping it in very large heaps—when in small heaps it dries without rotting, or only a small portion of it rots. When applied before the texture has become at all broken, the decomposition goes on slowly, especially in sandy soils, unless it be a moist season. For slip potatoes it has proved excellent, and one great advantage is that if followed by corn, the succeeding year no manure need be used. When the object is to improve the texture of the soil, mud ought to be applied. Directions for doing this are to be found in several of the numbers of this Journal, and need not be here repeated.

At Mr. Couper's we saw a very flourishing plantation of young olive trees, containing about two hundred. They appeared to be very vigorous, are from ten to fifteen feet high, and several of them have borne fruit for three years. A small quantity of oil was made from some of them, but the fruit has generally been pickled. We had the pleasure of eating some and found them excellent. These trees were nearly, if not all, imported from France several years ago, and have been found to stand our climate admirably, not being at all injured by the excessive cold of the two last winters. Nearly all the attempts made to propagate the olive, here, by cuttings, have proved unsuccessful, and this has been the case with all others of which we have heard, and we know of several. This appears somewhat strange, when it is known that in Europe it is propagated with the utmost facility. "It is multiplied by all modes that are in use for the propagation of trees, by sowing the seed, by layers, by slips, by cuttings of the root, and by sprouts separated from the trunk, or from the

roots of the parent stock."* And it is said moreover, "that if a bit of the bark with a thin layer of wood is buried in the earth, it becomes a perfect plant."*—Yet, in America, all of these modes have been tried and failed, or so little success has attended them that the culture of the olive is not likely soon to become a favorite. There is no doubt but that it would prove very profitable, and young trees might readily be procured from France—to commence with at least.—It might prove too expensive to form a large plantation of imported trees, but in that case, should we still be unable to discover some mode of propagation, the seeds might be planted, and when the young trees have become large enough, they might be grafted, and in due time, removed from the orchard to the plantation.

In France, it is usual to separate the stones from the pulp, after which they are cleansed in an alkaline solution, and sown in a sheltered situation in March, in trenches two or three inches deep, and covered with earth. "The young plants appear in October and continue to vegetate through the winter. By the following spring the most thriving among them will have attained the height of thirty inches. The feeble stocks should now be eradicated. With proper attention, and in favorable soil, the remainder will be four or five feet high, and six and seven lines in diameter in the course of the third spring, with a perpendicular root of thirty inches. This is the season for transplanting them. Great care should be bestowed upon the preparation of the ground, and the young plants should be placed three feet apart. After two years they will be sufficiently advanced to be grafted, and at the end of five years they may be transplanted to the olive-yard. To accelerate the germination, the stones may be kept in fine mold during the summer and autumn, and sown in the beginning of January. They soon begin to vegetate, and before the following winter the young stocks acquire strength enough to support its rigors, while the tender plant which comes up in October is in danger of suffering by the lightest hoar frost."

The only experiment we know of in this country to raise olives from the stones, was made by Mr. Couper, the account of which is contained in the following extract of a letter received from him a short time since:

"In the fall of 1831, I put some olives under a press and made a little pretty good oil; a part of the seeds or stones I drilled in rows about as thick and covered as deep as we do peas—none came up. I had, indeed, given them up and the patch was covered with crow-foot grass, when a few days ago, my gardener informed me they were coming up. I had the grass drawn out and find them rising as thick as thick as peas do. This experiment shows the facility with which any quantity of olives may be raised from seed."

It was with feelings of deep regret that we here witnessed the destructive effects of the winters of 1830, '31 and early part of '32, on what had been a most luxuriant grove of orange trees. It had occupied a space of twenty-two acres, regularly planted in squares, and bordered with sour orange trees. We do not recollect the age of these trees, but they had arrived at a bearing state, and had produced one most abundant crop and bid fairly, liberally to reward all the care and labor bestowed on them, when the cold of these winters completely blasted all expectations, destroying most of the trees to the roots and some entirely. We walked through the grounds where this splendid grove once flourished. Some few of the trees were standing, but in a wretched condition.—Most of them had, however, been cut off near to the ground, and were sending out vigorous shoots, which may hereafter restore the beauty as well as the profit of the place. The grove was bordered, as we have

already observed, with sour orange trees, and there were several walks formed by them, which in summer must have been very pleasant, as their tops met or nearly met, affording a delightful shade to those who might promenade through them.

Mr. Clarke, in a communication, published in the fourth volume of this Journal, objects to the use of sour orange trees for border screens to sweet orange groves, and states among other reasons that they are not more hardy than the sweet orange, whilst they are certainly injurious to them, and mentions several instances of this injurious effect. It appears to us, that the positions assumed by Mr. Clarke are correct, especially in the deleterious effects on all future groves formed from seedling trees. But from what we witnessed at Mr. Couper's, as well as in this city, we are inclined to think he has been rather too hasty in supposing the sweet orange as hardy as the sour. In this grove not a single tree of the sweet oranges escaped uninjured, and most of them were so severely so, as to induce Mr. Couper to cut them down to within a foot or two of the surface. Yet the avenues of sour orange trees suffered comparatively but little. The manner in which these avenues are formed, is worthy of a passing remark—the trees are in two rows separated about eight or ten feet. They appear to be from seeds drilled in the rows, and left as they came up without any being removed, consequently are extremely thick, varying from six inches to two feet. Yet, notwithstanding this contiguity, they are fine looking trees from fifteen to twenty feet high.

We here saw several date trees, one of considerable height—it is a female and more than twenty-five years old, blossoms annually, but bears no fruit. Several others are in progress, and perhaps, when these shall arrive at a proper age, fruit may be produced, though this is extremely doubtful as the leaves are injured by the frost. At Dr. Grant's (on this island) we saw about forty of them in one of his gardens, they had never done well, only one had borne fruit and that but once. We also saw the black pepper (*piper nigrum*) growing in the open ground in a vigorous state, it was covered up for the winter, and we could not, therefore, have a full view of it. It had grown, we suppose, three or four feet high, and appeared to be in good health. We believe it has never borne fruit, or not more than a few berries, owing to its having been injured by the severities of the preceding winters. From what we understood from Mr. Grant, we are inclined to believe it might be made, with a little care, to produce fruit.

At Mr. Couper's we saw the best collection and the finest vegetables we met with in this excursion. His turnips and cabbages were very fine, and one of the beds of cauliflowers was superior to any we had seen any where that season, some were fit for the table and the remainder promised well. There was one thing we noticed worthy of general imitation, which was a spot of ground planted with cabbages and cauliflowers expressly for the negroes,—(turnips being supplied from the general crop) These were as well attended and as well grown as those in the private garden, nor were the cabbages of the large coarse varieties, but on the contrary, such as were planted for the use of the family. The patch was surrounded by a common rail-fence sufficiently high to prevent cattle from getting in.

(To be continued.)

DRAINING

Constitutes an important operation in husbandry, and one in which we are lamentably deficient. Our wet grounds abound in the food of plants and constitute some of our best lands when discreetly husbanded. But in their natural state they will not produce healthy vegetation. The cultivated crops which we attempt to raise upon them are inferior and sickly, and as mere pasture, the grasses are coarse, sedgy and

* Essay on the History and Cultivation of the European Olive Tree.

Indifferent. Infertility is caused by the exclusion from the soil of air and heat, the essential agents in decomposing the food, and in stimulating the growth of plants. Hence the accumulation of vegetable matter in swamps. Draining operates in several ways to induce fertility. By carrying off the water, the soil becomes loose and warm; the food of plants is thereby rendered soluble; stagnant air and stagnant water, alike deleterious to vegetable and animal vitality, are got rid of, and a salutary and necessary circulation is afforded to air and water in the soil.

Grounds are rendered wet and unproductive either by the accumulation or retention of surface waters, or by the supplies of springs, which rise from below the soil. The first are remedied by a main open drain, carried through the lowest part of the ground, and by lateral ones, cut diagonally or at right angles with the main one, in sufficient numbers to drain the ground. The width should correspond with the depth, and the latter should in no case be less than two or three feet, and if practicable should terminate in the hard or subsoil. A drain 3 feet deep, 4 feet broad at top, and one at bottom, exhibits good proportions. Lateral drains may be somewhat smaller.—The earth taken from the drains should be thrown back and spread, or carted off, that the surface water may freely pass into them. If the earth is peaty, or what is termed muck, it affords an excellent dressing for uplands. It is soon converted into food for plants by its admixture with earths, particularly sands.—Care must be observed to keep the drains open, and to remove obstructions to the free passage of the water. An economical method of keeping drains in order is to practice what is called *scurving*. It is performed in the summer months, when showers have produced an abundant flow of water, by men commencing, with loes and spades, at the upper end, and passing down in the drain, loosening or throwing out in the way, the earth and other obstructions which have accumulated there. The current, then, greatly facilitates the cleaning operation.

The business of ditching, like every other branch of labor, is improved by practice and by system. An experienced hand will not only perform more than one who is raw, but will perform it much better. It is important to preserve the slopes entire and unbroken. To do this successfully my practice is, in the first place, to draw a line on the two exterior edges, and to cut the depth of the spade on these lines, in an angle of the intended slope. In the next place the operator takes a spit from the centre, and so far from the outside, that the perpendicular cut shall not disturb the earth below the slope. When the centre is thus thrown out, the face of the slope is then readily and symmetrically formed; and a second spit then taken from the centre as before, and the operation thus continued until the drain is finished. The price of a four feet drain varies from eighteen to fifty cents per rod, according to the soil, and the obstructions which are to be operated upon. The best season for cutting open drains is August and September, because there is generally less water then to encounter, and that the slopes have time to dry and consolidate before the frosts of winter.

(From the Genesee Farmer.)

LEACHED ASHES.

Messrs. Editors: *Potter, April 15, 1833.*

I have known many vessels to arrive at various landings on the Hudson to engage teams and haul leached ashes, from two to six miles, to transport them to Jersey, Long Island and Connecticut.—land, and sell them at from eighteen to twenty five cents a bushel, to be carted from two to ten miles, and used for manure. It is clear then that these men were very much mistaken, or leached ashes are a valuable manure. They are said to have grown rich by it.—I can see, therefore, no reason why they should not be good manure in Western New York. I have my-

self used them for many years, both in my garden and in the fields, and always with satisfactory results.

I believe that leached ashes are as good if not better than unleached ashes, as their fertilizing qualities do not depend on the quantity of alkali contained in them, but on other principles derived from the atmosphere, and that they are as good after lying fifteen or twenty years as if used when fresh from the leaching.

I have said that the modes of applying leached ashes are various. They are applied on the surface, spread and turned in with the plough. In this situation they operate powerfully in reducing the grass and roots to the food of plants; they also attract much fertility from the atmosphere and I believe them to be good on most lands, whether clay or sand, whether moist or dry. They are also used in compost, one load of ashes to two of stable manure, and two of soil, they are also used as a top dressing to corn after the first hoeing; half a pint is scattered over each hill, and has all the beneficial effects of plaster.

Such is my experience and observation on this subject, and remain, Yours, with respect, R. M. W.

HORTICULTURE.

(From the Genesee Farmer.)

VEGETABLE PHYSIOLOGY.

MR. L. TUCKER:

In compliance with your request, I forward you the following essays for publication, in the Genesee Farmer. They were delivered as part of a course of lectures before the Buffalo Lyceum about a year since. They were written in haste and without method, and were intended only to throw out general views, and such information as would draw the attention of our citizens to the subject of embellishing their own grounds with trees, fruits and flowers. Many observations contained in them have been already published in the Farmer, but they are here made necessary, to give a connected view of the subject. Respectfully, yours, ULMES.

ARBORICULTURE.

The science of Vegetable Physiology, if science it may be called, taken in connection with its attendant arts, although by many considered of humble claim to the attention of the community, is yet one of great utility and ornament. Dating an origin nearly coeval with the earth itself, and associated, as its vast family ever has been, with all that we know of the beautiful and sublime, it has long numbered among its devoted admirers names illustrious in wisdom and science. The man of ordinary walk in life, and the more humble laborer, realize in its various productions much of enjoyment and satisfaction, while the fairer part of creation have loved to cultivate with their own hands many favorite productions of the vegetable world.

Poets have sung their praises—sages have expatiated on the magnificence and splendor of their varied productions—moralists have drawn rich truths, and discoursed charming lessons of instruction, from the pure models of vegetable art with which they were surrounded; and much that ourselves possess of virtue and intelligence has been drawn from the study of moral nature. As, however, we do not propose solely to theorize upon the subject before us, we shall at once proceed to take a popular view of the science.

Agriculture signifies the cultivation of the earth for the purpose of obtaining its vegetable productions. As branches to this science, belong arboriculture, or the cultivation of trees—horticulture, or the improvement of gardens, and floriculture, or the cultivation of flowers. The varied productions of all these branches are subjects of the more general science of botany, which

relates to a regular and systematic arrangement of classes, genera, species and relations.

Our present attention will be more particularly confined to arboriculture, or the cultivation of trees. We shall endeavor to show, in a plain manner, the grand operations of nature in forming and rearing her most beautiful and splendid embellishments—their relations to each other, and the different functions of the several parts of the plant—their uses and properties, and how we can avail ourselves of the various parts for the propagation of their species—transferring them from one situation to another—and the very simple manner in which they may be reared to early maturity, embellishment and usefulness; and we most earnestly wish that the whole subject might be rendered “familiar as household words.” that immediate practice should be the result of our observations.

Naturalists have wisely said, that they hardly knew where to draw the line of distinction between animal and vegetable life. The almost innumerable instances of zoophytes, madrepores, and sponges of the ocean, as well as the various family of fungii that we continually see springing from the earth, add to our difficulty in making the distinction; and the abstrusest studies of scientific scholars have only created new doubts in their minds, and more firmly seated their previous ones. Even the power of locomotion, which some have assumed as the basis of distinction between vegetable and animal life, gives no conclusive proof on the subject, so remote may be its power of action.

Irritability in the object has been assumed to mark the distinction; but if the oyster contract its shell upon the touch of your finger, so does the locust and the sensitive plant. The naturalist, even when intently examining what he had fondly hoped a new vegetable of rare appearance or rich promise, has detected brain and spinal marrow! If you assume as a distinction, the multiplication of vegetables by cutting them into numerous parts, and giving each its proper place in the soil, so may you divide the polype-fish into a thousand pieces, and restore it to his native element, each will assume a distinct being, and soon be resuscitated into perfect shape. Many vegetables too have no seeds, and many animals produce no eggs or progeny. The ancient Aristotle, and the modern Boethave, after years of laborious investigation and profound study, declared plants to be animals, merely turned inside out! And the whole collected wisdom of the present day on this intricate subject, after years of patient research, commencing with confidence and hope, have ended in complete doubt and dissatisfaction.

I do not know that we can better illustrate the starting point of distinction, than to take as common and shapeless a thing as a mushroom, the farthest remove of vegetable existence. Let the slightest graduation be made from it on either side into animal or vegetable life. Let these almost imperceptible changes be followed up in successive gradations, each assuming their separate distinctive qualities in a greater degree as they advance, until one had assumed the perfect form of a man; and the other had acquired the finest development of the vegetable world.—This may appear mostly imagination, but in the many gradations that we pass, might we observe the sponge, the coral, mollusca, toad, and so on, through various quadrupeds up to our own fair likeness; and on the other side should we note various rude and uncouth vegetables, gradually waxing into comeliness and form, until the almost perfection of vegetable life had been obtained.

Trees almost universally are propagated by seeds like other plants. In some instances, however, the production of flowers, fruits and seeds, have thus far escaped detection. Yet even in these their existence may have escaped observation, for nature has so many secret stores in her vast laboratory of reproduction,

• Class, *Cryptogamia*—order, *Fungi*.

that where the positive test of sense, or the unerring result of chemistry, is wanting, we can be clearly certain of but little. Seeds, as we all know, are the ultimate ends of vegetable life. They are the perpetuating links by which the innumerable varieties of vegetable nature are sustained, and a minute examination into the tenacious living principle of some of these has been the cause of wonder and admiration. The germinating principle of seeds, and plants of particular kinds, has been ascertained to be capable of full and vigorous development after a close incarceration of two thousand years! Familiar examples are continually accruing, under our own immediate observation, of plants shooting into life from seeds which must have been deposited in the soil many centuries ago. We have only to cast our eyes on the fields around us to witness the white clover, the thistle, the fire-weed, and numerous well known plants, occupying the ground recently covered by the forest. If these productions be supposed to spring from recent deposits of seeds from older fields, go into the deep wilderness, miles and miles from any settlement—cut down a few acres of timber, and apply fire to its extinction,—immediately will come forth grasses and weeds not to be found in the whole region around you.

Do you wish to investigate the matter farther? Let the ground remain, and visit it again at the end of five years. You will find a rank growth of young wood of altogether dissimilar kind to that which had been cut away. Pine often succeeds to the oak, and oak to the pine. To the chestnut may succeed the poplar, and sugar maple the walnut. Or one given kind follow after another in almost endless variety.—These plants we know certainly spring from seeds in the ordinary course of vegetable life, and we have no authority to suppose that they vegetate in any other manner. The seeds from which all these plants spring must have been deposited, no doubt, by trees producing the same kind, which in far earlier time had occupied the same ground, and, for want of the peculiar qualities of soil, atmosphere, humidity or warmth, to nourish them into life, had preserved, through this long stage of dormant existence, their germinating qualities in full perfection.

These facts, to those unaccustomed to inquire into the seeming mysteries of the creative world, may savor of the marvellous, but it is not more remarkable than that a living toad should have been discovered encased in a solid deposit of limestone, several feet below the surface of the earth. Yet such we know to have often occurred. A lifeless mummy, of the times of ancient Pharaoh, after an incarceration of two thousand years in the vast pyramids of Egypt, has been exhumed from its resting place—divested of its waxen cerements, and exhibited to the gazing world, an object of wonder and astonishment. It has been a subject of profound contemplation to the moralist, of abstruse speculation to the philosopher, of delightful recollection to the scholar, and of sublime apostrophe to the poet! But to the inquiring naturalist, it is matter of more absorbing interest to contemplate the history of the humble animal I have mentioned, or to view, expanding into beauty, flowers reared up from seeds which perchance might have bloomed and ripened in the spicy gardens of Solomon.

The *germinating*, or living principle of seeds, is protected by an outer case or shell, and may be preserved as has been remarked, to an almost indefinite time. But to produce its kind, it is committed to the earth in the ordinary process of planting, a course too familiar to need remark. Stimulated into action by the genial warmth of the ground, and excited by the operation of gases and moisture, it wakes into life, and becomes a living plant. By degrees it assumes its specific form and character, and passes from mere vegetable infancy into its perfect genuine state. It is now divided into three principal divisions, of root, stem and leaf, each of which possess their own peculiar functions and properties.

The *root* of a plant may with propriety be termed

its seat of life, as from that its first principles of sustenance are drawn. At the time when the seed first germinates in the ground, the same part of it which throws up the shoot from the ground, also sends into the soil below a corresponding share of root to yield it support. The flesh of the seed, or that part which is attached to the germ, now in a state of decomposition, gives nourishment to the tender shoot until it has acquired strength to draw its sustenance from the earth. The remaining part or husk of the seed, is then rejected, and the soil is its sole support. The root is of a soft and fibrous character, full of minute veins and pores. As it grows in size and vigor, it throws out thousands of minute tendrils, which creep through the best portions of the soil, and serve as so many mouths, or feelers, to collect and absorb food for nourishment to the plant. The roots are provided, like the trunk and branches, with heart, albumen, or in common parlance, with sap-wood and bark. As these grow into main roots, and increase in size and age, they become hard and less susceptible, and merely serve as a support to the trunk and branches, and to convey the food from the younger and distinct portions into the body.

The *heart* is another part of the wood, and constitutes a larger or smaller proportion of its bulk, according to the kind of plant in which it exists. It is porous, but more compact and dense than any other portion of the wood. In young plants it is exceedingly small. As the plant progresses, however, it increases in size from an accession of the inner albumen, or sap-wood; and in time becomes, according to the nature of the tree, the greater or lesser portion of the wood. For many purposes it is considered the most valuable part of the whole. From the smallness of the pores and closeness of the grain, but little sap, or vegetable blood, passes through or is found in it; and for that reason this portion of the tree or vegetable, may, in part, or wholly, decay without serious injury to its growth. It is usually of a brown color, and easily distinguished by its otherwise hard and compact properties.

The *albumen*, being that part of the tree or plant which surrounds the heart, and within the bark, is usually soft, open and porous, and of a white delicate color. In many kinds of wood, such as the poplar, linden, maple &c., it comprises a large proportion of the bulk, while in others, as the red elm, oak, hickory, &c. it is a thin formation around the heart, and is of less utility as an article of timber, but altogether essential to the life of the tree. The sap, which is absorbed from the soil into the roots, passes up through the albumen into the branches and leaves. Trees having a large proportion of albumen are more tenacious of life than those having much heart wood, and therefore serve more valuable purposes for transplanting, and in many instances are exceedingly valuable for purposes of timber.

The *bark* is the outer covering, and composed of strong elastic fibres, interwoven with each other in the most complex manner, resembling often times curiously fabricated cloth. These fibres are hollow, and their office is supposed to be to convey the *elaborated sap* from the leaves down along the body into the roots of the tree, as will be hereafter noticed.—The bark is an essential part of the plant, and without it no vegetable can exist for any length of time. While the full juices of the plant are in operation during certain portions of the year, if the bark be slipped from the trunk, so active is the flow of the sap, and so rapid are its secretions, that a new and perfect bark is quickly supplied. During the summer a new circle of albumen is deposited around the body of the tree, which is no doubt a secretion from the *elaborated sap* through the inner pores of the bark. This is denominated the *grain*, and in ordinary cases the age of a tree may be ascertained from the number of circles or grains lying between the centre of the trunk and the bark. Another very important function is attached to the bark. As the plant or tree

advances in age it becomes thicker, and the outer part ceases to perform its duty of circulating the alimentary fluid, and it now serves for a protection and shelter to the inner bark and wood. It partially becomes an excrecence, and falls in detached pieces from the tree, as is often observed in the shell-bark hickory, sycamore, wild cherry, and the honey locust. A close examination of the formation of barks with a microscope might furnish abundant food for curiosity. Its various and intricate texture, the winding of its attenuated and silken fibres through each other in such sinuous and complicated forms, is a matter of infinite ingenuity and wisdom. How many minds among us all are sensible that the finest thread in a piece of linen cambric, is composed of several fibres, each having a distinct hollow pore, which has served, while blooming in the field, to convey aliment through its system!

The *leaf* is the most ornamental, and not less than others, an essential part of the plant. It is composed of a petiole, or foot stalk, which attaches it to the twig or limb. This petiole is composed of hollow fibres or tubes, and at the point of expansion into the leaf, diverges into an infinite number of minute prongs and branches, which again diverge into numberless threads leading to the extremities of the leaf. These fibres are enveloped in a singularly curious vegetable web, constituting the surface of the leaf. This surface is filled with an immense number of pores, through which it receives its proper food. It is estimated that from fifty to one hundred and fifty thousand of these pores exist in a single leaf. A continual evaporation of moisture and oxygen gas is going on throughout the day from their surfaces, while their food, which is supposed to be carbonic acid gas, is absorbed through the pores of the *under* side of the leaf. These operations will presently be noticed.

All plants, as we have seen, are endowed with organs which enable them to receive, digest and assimilate their food, which is indispensable to their growth, maturity and reproduction. Various and contradictory opinions have been advanced by eminent philosophers and naturalists as to what constituted their true and proper food. Some contended that water was the sole food of plants. Others that pulverized earth constituted it. Others again have asserted that the gases—and others yet, that oils sustained them.—From experiments, however, made within twenty years past, it is more safely to be supposed, that the substances arising from the decomposition of vegetable and animal matter, or *carbonic acid gas*, constitute the true food of plants. This food exists in the soil, in the water, and in the air, which are all more or less charged with it, as they have come in contact with those substances emitting it. When it exists in the soil, aided by caloric or heat, it is conveyed by humidity into the roots; and when in the air, by pure gases into the pores of its leaves and young bark.—Like animals, their various organs perform distinct functions of support. The degrees of nourishment taken by the various parts of the plant differ in many kinds, yet each part has its particular office assigned it.

It is only on chemical principles and personal observation, so far as they go, that we can arrive at certain conclusions in this intricate matter. A few negative propositions perhaps may not be amiss in disproving the above named opinions on the sustaining principle. That *pulverized earths* are not, is evident from no earthly substance being detected within the bark of a plant. Besides, the common earths simply, such as clay, lime, magnesia or silice, aided by air and water, will not support vegetation. *Pure water* will not sustain vegetable life for any length of time. It may indeed sustain it for a while, but when the specific nourishment derived from the water as a component part of its food is expended, the plant will die. *Pure gas* may be subject to the same remark. And the idea of *essential* oils being the sole sustaining principle of vegetation will bear no close investi-

gation. If, however, to the earth's first mentioned, and they are rarely to be found unless more or less mixed, be added vegetable or animal matter, the moment that they receive the impulse arising from the decomposition of that matter into its original elements. (*carbonic acid gas*.) the process of vegetation will commence, and until decomposition takes place, the vegetable principle remains totally inert.

Assuming, therefore, *carbonic acid gas*, operating through the medium of mixed earths, water, and the atmosphere, as the proper food for plants, it remains to observe the manner of converting it into vegetable nourishment. The roots, ramified as they are into numberless attenuated fibres, and buried beneath the soil, acting on the principle of capillary attraction, absorb the moisture from the earth charged with gases, and convey it through the minute pores with which they are furnished into the main roots. During the process of passing through the roots, this moisture is elaborated into *sap*, which passes up principally through the alburnum into the branches and leaves. And here the peculiar province of the leaves is displayed. They are the *lungs of the plant*, and a continual course of respiration is passing on through their numberless pores. A portion of the ascending sap now passes off by evaporation through the surface of the leaves, while from beneath, or the underside of them, *carbonic acid gas* is absorbed from the atmosphere, which, mixing with the remaining sap, and assisted by light and heat, is elaborated into a colored or mucilaginous fluid or blood, denominated *elaborated sap* or *prepared juices*. This is distributed back through the system by another channel, generally supposed to be the inner bark next the wood; and in trees, deposits annually, as before observed, a circle or grain of new wood around the stem or branch.—This blood also produces new branches, roots, leaves, and buds. Bark itself, if young and tender, is partially endowed with the functions of leaves in absorbing food from the atmosphere; being alike supplied with pores—a wise provision of nature in enabling the branches to clothe themselves anew with foliage on extraordinary occasions.

To demonstrate the fact that the vegetable blood, or prepared juices, descends through the inner bark: If a small circle of bark be cut from a branch, unless the bark form anew and unite, the extreme branch increases to a much larger size than that next the stem; because it is continually receiving its due proportion of sap through the alburnum, which is elaborated at the leaves; not being able, by reason of the separation of the bark, to return into the body. The vegetable blood being confined here, will cause an extraordinary accumulation of fruit buds on the branch. Hence the practice of *ringing* the branches of fruit trees, as it is called, to cause a greater production of fruit. This blood also supports the flower and fruit, and ultimately perfects the plant.

That the sap, after passing up from the roots, ascends the wood through the alburnum, is evident from a very simple experiment: If an oak, the alburnum of which is quite thin, be girdled to the heart, it immediately dies. A bass-wood, or maple may be girdled to the same depth, but as they possess a much greater proportion of alburnum, and are of course more tenacious of life, they will perhaps live through the season, and possibly throw out a weak and stunted vegetation the succeeding year; but death soon must follow.

These elaborated juices no doubt give a distinct character to the plant; each of which is distinguished by its own peculiar taste and smell. The pine has its turpentine. The fir has its balsam. The maple its saccharine quality. The butternut its strong coloring and medicinal properties. Why these characters are given them, is one of the yet untathomed secrets of nature, and like the causes of color in flowers, is hidden from our knowledge.

For immediate practical advantage, and to aid the planter in his operations, the following observations, partly of repetition, may be proper:

The earliest food of plants is absorbed by the roots, and there being elaborated into sap, ascends through the alburnum of the stem and branches into the leaves. It is then, in a certain portion, evaporated through the pores of the *upper surface* of the leaf: the remainder is then elaborated by the action of carbonic acid gas, absorbed through the pores of the *lower surface* of the leaf and new twigs of wood, into vegetable blood, or prepared juices, and then descends through the inner bark again to the roots. This prepared juice also supports the flower and fruit. To show how necessary the several parts are for the support of each other: If a portion of the roots be cut off, the growth is checked. If the plant be stripped of its leaves, the same result is observed. The growth of a plant is promoted in proportion to the quantity of sustaining matter it may receive. If the soil be heavily charged with rich deposits, a vigorous growth is the consequence; and the more open, free, and generous the soil, in so much greater proportion will its growth be accelerated. If a superabundant portion of vegetable food be mixed with the atmosphere, the effect of its influence on the growth of the plant is in proportion; and hence may be accounted for the huge tops of many trees in the streets of our cities, which are supported by such slender stems, and whose roots are sustained beneath a pavement. We observed that the living principle is excited by heat. In the spring, on the approach of warmth, the juices of the tree are found, by the chilling influence of winter, condensed and lifeless. The sap is now started into life, and increasing warmth infuses animation into the whole vegetable system. Through the summer, the various functions of the plant are performed, and its growth perfected. In autumn, as its powers are expanded, its active functions slowly terminate—a great portion of its sap passes off by evaporation, and the leaves fall to the ground; and in process of time return to their original elements to give new life and action to the beautiful structure which they once aided to adorn. So is this admirable operation of nature carried on from one change of season to another.

From the foregoing observations, the arborist will readily understand the governing principles that should guide his operations. It therefore remains to drop a few hints to govern the immediate selection, removal, and planting of trees:

1. Those trees having a large portion of alburnum in their composition, are more tenacious of life; are earliest in leaf in the spring; retain their foliage latest in autumn; and are generally of more rapid growth than those kinds which have the greater proportion of heart wood.

2. In taking trees from the earth, great caution should be used to prevent injury to the roots and trunk; and as many of the fine roots as possible should be retained. Should they be broken and imperfect, they should be smoothly cut off with a knife.

3. In all cases when a tree is transplanted, let the top bear a due proportion in size to the root; each being a mutual assistance to the other in perfecting its growth.

4. In selecting trees for transplanting, *never* take them from a dense, high forest, when they can be otherwise obtained. Owing to their local situation, they have few roots, and those long and straggling; their tops are proportionably slender and thin; and being accustomed to the deep shade of the surrounding trees, and for want of acclimation, they in most cases die when exposed to the heats and winds of open grounds.

5. Trees for transplanting should in all instances where practicable, be selected from open, exposed situations, where abundant opportunity was given them for an expansion of root and branch.

6. Let the soil into which they are transplanted be as near as possible like that from which they were taken; but if poor let it be enriched.

7. Let the hole for receiving the tree be two or three feet larger in diameter than the roots, in all cases.

Let it also be at least a foot deeper. Fill it partly up with good light soil. Set the tree so that it shall stand when planted, not to exceed two inches deeper in the ground than it stood originally. Let one person hold the tree firmly in its place, while another throws carefully the earth, well pulverized, and made rich, on to the roots.—Let it be gently swayed back and forth while filling up, that the earth may mingle well with the roots; tread it firmly around the stem when finished; then secure the whole with good and sufficient stakes; and in nine cases out of ten, the tree will live and thrive apace. Whenever practicable, turn the wash of the roads, or from other places, on to them. It accelerates their growth in a superior degree to any other nutriment.

That so great a number of trees which are annually planted in our streets and open grounds perish, is from the neglect of the rules thus laid down. In many cases the planter is profoundly ignorant of the subject; and in others, too sparing of expense or labor in planting. In all cases where it is *determined* that trees *shall grow*, true economy would dictate the planting on strictly scientific rules; as in all cases of failure, the labor has to be renewed, and the growth of the tree is lost.—Common sense, therefore, as well as prudence in expense, requires a practised hand in making all plantations.

In cases of stunted and imperfect growth, and where trees are infested with moss, the only resort should be had to the soil and roots, and scraping the stem and branches clean, and washing them with lime water, or other strong fertilizing mixture. If the soil be hard, or sterile and worn out, let it be extensively loosened with an iron bar, fork, or spade. Let rich compost be dug in; water applied; and occasional attention bestowed; and the plant will forthwith renew its vigor and growth. The vulgar opinions of splitting the bark, clipping the branches, or in fact, any thing but the application of wholesome stimulants, except in cases of disease, is worse than idle.

A few general remarks will close the subject.

A love for the cultivation of trees, has often been remarked as evidence of a refined and enlightened mind. At an early period of the world, they attracted the care of the husbandman; and they are named in terms of commendation by the earliest writers. The man of science, as well as the philosopher, has devoted years of study to inquire into their hidden qualities, and to discover their natural history. The world has been traversed to find out new species; to ascertain new facts in their development, or different properties in their composition. They are made subservient to our use in various ways, and from their bark and leaves are obtained many of our drugs, our ornaments, our physics, and our dyes.—From their woods are derived many of our choicest comforts of food, raiment, habitation, and fuel;—and who, of natural and animated feeling, but loves the association of their name?

Healthy, well formed, stately trees may truly be called the finest models of vegetable creation. They are every where—in all lands, and among all people, subjects of deep, delightful study. They have been planted, nursed, and trained with almost paternal care. Their cool and pleasant shades, their classic forms, their splendid flowers, their magnificent foliage, and delicious fruits, have administered to the pleasures of the sense; and the contemplation of their majestic verdure, standing apart, or in groups, amid the quiet landscape, a silent yet living monument of the vast opulence of creative power, has often led the mind into the most sublime and solemn reflections.

The Roman Virgil sung the sweetest verses of his Georgics while basking in the groves of his own sunny Italy. The poet Milton loved to meditate beneath the deep shadows of his native trees, and some of his rarest numbers were breathed in admiration of their beauty. The amiable Addison drew many of his most instructive meditations while musing beneath the mighty elms of the Covenly domain. The classic Thomson,

while luxuriating in the repose of "Woody Richmond," and stretching out his lazy length "to pore upon the brook that bubbled by," built his gay castles in the sunny clouds, and wrought out those splendid images that surround his "Castle of Inguenoe." Even the great bard of Avon, "the noblest Roman of them all," has drawn his sweetest discourse from the lips of the noble, melancholly Jaques, as he sat soliloquizing amid the deep forest of Arden.

Our own country too, has furnished rich examples of devotion to the beauties of vegetable nature. The illustrious Washington often declared that his purest pleasures were derived from contemplations among the groves of his own shady Vernon. The philosophic Jefferson received the homage due to exalted genius, surrounded by his native oaks at Monticello. And Patrick Henry, the Demosthenes of America, in his declining age, loved to sit in the warm summer evenings, under a mighty Black Walnut that stood before his dwelling, and give sound lessons of instruction to his friends and neighbors in the science of free government.

Even savage man is feelingly alive to the remembrance of his native trees. With what delight does the swarthy Ethiopian view, while afar off, his magnificent Palm trees, on returning from his journeyings in the desert! How grateful is the heart of the simple Hindoo while enjoying his repose under the far spreading branches of the Banyan! And with what unconquerable love of liberty does the Canadian savage leave the haunts of civilized man and seek his rude dwelling among the giant Pines of his native forest!

Who then possessed of means and opportunity, would neglect to embellish his grounds, and perform a sacred duty to himself and his fellow men by planting a few trees, and rearing them up, green perennial monuments to transmit his memory down to a grateful posterity? The occupation is surely a happy one; and the time devoted to their culture might all be drawn from that too often spent in idle pleasures or trifling amusements. Their cultivation excites the mind to a love of study and inquiry; and a walk beneath their cool shadows has often administered consolation to the bowed down and afflicted. They afford a shelter from the oppressive heats of the sun, and from the violent winds and storms which often assail us. They beautify our dwellings, our grounds, and our streets. They give an appearance of wealth, hospitality, and domestic enjoyment to our possessions which nothing else can supply.—They also, by the process of absorption, carried on through their foliage, relieve the atmosphere of those noxious gases which float up from impure accumulations, and which might otherwise be injurious to our health.

Let every one then, possessed of ground, immediately commence a duty so interesting in its performance, so beneficial to ourselves, and so useful to our successors. Let the waste places be made glad, and the naked hills be clothed with verdure. Every spring shall see them put forth their green leaves, and the air shall be made fragrant with their opening blossoms. To the wayfaring man shall their sight be most refreshing, "like the shadow of a great rock in a weary land!" The earth we possess is beautiful in its soil and its verdure; in its rocks and its waters; and to add new charms to its surface, may well be called a virtue. With what serene pleasure does the good man in the evening of a well spent life, walk out under the broad shadow of the trees he had long ago planted! How cheerfully does he gaze upward at their spreading branches which his own hands have fashioned, and which shall in future ages invoke blessings on his beneficent head! And with what calm solemnity does he look forward to the time when his own lifeless trunk shall be carried out for sepulture beneath their leafy coverings, then throwing over his remains a magnificent funeral canopy!

Let the cultivation of trees become more established in our country, and instead of the bald and cheerless appearance of many of our farms and villages, cool,

delightful shades would greet the eye. Pleasant, calm retreats would offer consolation to the troubled spirit. Majestic columns of splendid vegetation would throw aloft their whispering foliage, and spread their shadowy arms over our peaceful dwellings; and thus, by our own kindly assistance, render our clustering habitations and gardens like so many Edens scattered through the land.

RURAL ECONOMY.

(From the Virginia Farmer.)

ON CUTTING DOWN AND CLEANING UP THE MARGINS OF RIVERS AND CREEKS, &c.

MR. McROBERT: *Spring Hills, April 8, 1833.*

I have thought that probably a few remarks upon the subject of cutting down and cleaning up the margins of rivers and creeks, together with some hints in relation to straightening creeks and branches, might find room in the Virginia Farmer.

For the last six or eight years I have been but seldom from home, at least so far as to be out of hearing of my own dinner horn, but within that time, (previous to that I never noticed such things,) I have seen farmers bordering upon rivers, or enclosing creeks with standing timber—trees of all sizes on the banks. Upon inquiry, it would be told me that they were left there to keep the banks from washing. Now this is a great mistake—I speak from experience.—Trees growing upon the bank shade the ground and prevent the perennial grasses taking possession so as to form a sod impervious to water, which would be the case if the trees were removed, and not only kept from washing, but every fresh would leave more or less deposite, until finally, as much land may be made into the river, as the width will justify. At particular situations, where the water, owing to a curve in the stream, may have an unfavorable bearing, a small willow growth in the water's edge may be admissible, to form a base for the bank, i. e. to prevent an abrupt or perpendicular bank which is never secure. The banks must be brought to a gentle and regular slope, and then, if they are permitted to stand to grass, they will be gaining something every freshet. By attending to the above precautions, I have made several corn rows along the river bank within the last seven or eight years. On the other hand, when the trees are standing, they not only obstruct the current to the amount of their own magnitude, but catch large quantities of drift wood, forming hammocks which produce a whirling and dashing about of the waters, washing up large holes at different places, and causing great inequality of the banks; and last, though not least, often throw the main current into the adjoining low grounds, taking off the improvement of many years at one single freshet. In addition to all this, the crop is injured by the shade from these trees, to say nothing of the loss of ground on which they stand. It is true, an overwhelming freshet is a formidable opponent: for that reason, let it pass as smoothly and uninterruptedly as possible and it will do you the less harm, and indeed (save the fencing) if your grounds should chance to be fortunately situated (clothed in grass) at the time the freshet comes a great deal of good. To this end keep every thing that is capable of offering any resistance to water, cut clean. In felling the native growth, cut as low as possible, especially such as is of lasting quality.

What I have said of river banks, will apply with equal force to creek banks, or those of small streams running through our fields.

A word now as to the manner of straightening creeks and branches. Some times in doing this work it is desired to turn as much low grounds into a body as possible, and for that purpose, the stream is conducted to one foot of the hill or the other, and for the furtherance of the object depart from a straight direction, winding with the hill. Now unless this hill is

a cliff, or certainly never to be cultivated, this is also a mistake, for in working the hill, every move given to the dirt it tends towards the branch, and there being no resting place, is finally lost in the branch.—When it is desired to change a stream where the opposite hill sides are cultivated, it is generally best to conduct it (having due regard to continuing a straight course as far as possible) as near the centre of the vale as may be convenient, in order that if any thing be lost off the hills, the bottom may catch it.

It is the practice with some farmers when they change a creek, to make permanent and high dams at every place where the new crosses the old way, in order to force the water in tides to go the new way.

I think I have profited by a contrary practice. I make very slight slopes, if any at all, so that when the water comes, the strong current (which carries the heaviest and poorest alluvion) may take the new straight way, and the weak current (which carries the richest and best) take the old way, thereby depositing a quantity of sediment towards the speedy filling up of the old bed, and when once filled up by these means, will be land of the first order. But if you shut the water entirely out, should you want it filled up, you must go and haul dirt.

I must come to a close, but first I must be permitted to offer an apology to you, and to the readers of the Farmer, for troubling you with my poor communications. It is this: We have all heard it said, "Now the ice is broken," &c. I have, Mr. Editor, broken the ice, in hopes that others (and many there be) who must know that I am not able to teach even what I might know, would take the subjects in hand. If so I know I should be amply paid for my labor of writing, though, to me, rather an irksome task. And now (I believe I am at the right place in my scroll) I must take occasion to congratulate you, and your readers, on the addition lately made to your best of correspondents. I mean "A Buckingham Farmer." His "Fire-Side Reflections" is the best article, as far as it goes, that I have seen. Do request him to give us his practice in minutia. I should be glad he or others would say something about the best mode of draining wet land—such I mean as has many springs which are to be ditched out, and then secreted to an open drain. The difficulty with me has been this: After ditching so as to take in all the water, and blinding, (as we here call it,) either the blinded part would stop up after a few years, or the water would rise in another place so as to render the land wet about those springy places. I would like to know the best mode of blinding or secreting ditches.

I have several objects under consideration, but am much engaged about this time, having just commenced ploughing my corn lot, and it now affords plenty of grass for twenty head of cattle when the ground is dry enough for them to be on it. I expect if you were to see it, you would be scared for me, but by the blessings of heaven, I don't fear yet.

I am, respectfully, yours, JAMES T. JONES.

SIR ARCHY.—This famous horse has cleared for his proprietor (independent of his achievements on the turf) \$70,000. He is still living, but in the extremity of old age, (in the 30th or 31st year.) His vigor is extinct. He has not shed his hair for several years, and it has grown to the length of two or three inches. A gentleman who has lately seen him, says, that of all animals, he is the worst looking, and would be the last taken for the most celebrated horse of the age.—His owner treats him with all possible kindness, as it would be unpardonable, indeed, if he did not. Provider without stint, at rack and manger, and a soft and delicate bed, proclaim the proprietor's gratitude. The door is left open to allow his egress and ingress at pleasure, but it is observed that Sir Archy only comes out to drink, and having done so, immediately returns to his stable. Except those of the finny tribe, it is conjectured that Sir Archy's posterity outnumbers that of any living animal.—*Richmond Whig.*

THE HORTICULTURAL SOCIETY OF MARYLAND,

For the diffusion of Horticultural Science and the Improvement of the Art of Gardening; Associated Nov. 20th—Incorporated by act of the Legislature, at December session, 1832.

The Council of this Association have resolved to open the public proceedings of the Society, by an Exhibition of Plants, Flowers, Fruits and other Vegetable productions.

The Exhibition will be opened on the eleventh day of June next, and will continue during that and the following day.

On the eleventh of June, popular lectures will be given in the hall of exhibition, and on the twelfth the society will hold a public meeting, when an address will be delivered.

In furtherance of the views of the society, the Council have resolved to offer premiums to the aggregate amount of one hundred dollars, to be awarded to the finest objects exhibited, by a committee of Judges appointed for that purpose.

The following gentlemen have been appointed to act as committee of arrangement, viz: H. F. Dickhut, chairman, Z. Waters, Geo. Fitzhugh, James Moore, Edward Kurtz, I. I. Hitchcock, Sam. Feast, John Feast.

All who feel interested in the advancement of Horticulture, are invited to lend their aid in furtherance of this design. Those wishing to exhibit plants or other objects of Horticultural interest, will please communicate their views to the committee of arrangement, stating at the same time the articles they design to exhibit.

Letters on the subject, must be addressed to the chairman of the committee, from whom any further information may be obtained.

May 3.

Prices Current in New York, May 11.

Brewer, yellow, 18 a 20. Cotton, New Orleans, 11½ a 14½; Upland, 10½ a 12½; Alabama, 11 a 14. Cotton Baggins, Hemp, yd. 13 a 24½; Flax, 13 a 14½. Flax, American, 7 a 8. Flaxseed, 7 bush. clean, 15.00 a 15.25; rough, 13.00 a —. Flour, N. York, bbl. 5.50 a —; Canal, 5.50 a 5.75; Balt. 200,000 WHITE MULBERRY TREES.

The Subscriber has on hand and for sale 200,000 White Mulberry Trees of two and three years' growth, which have been transplanted, are in a healthy and thrifty condition, and which he offers for sale at \$1.50 and \$2.00 per hundred, delivered at the nursery.

Also, a few of the Morus Multicaulis, or Chinese White Mulberry.

ASA BUTLER,

Suffield, Connecticut.

P. S. All orders (post paid) will be punctually attended to. April 12,—bt.

WHITE MULBERRY SEED, &c.

Just received at the American Farmer Office and Seed Store a supply of fresh and genuine WHITE MULBERRY SEED.

MAMMOTH PUMPKIN SEED.

EARLIEST FRENCH CABBAGE do.

EARLY FRENCH, or PARIS WHITE ONION do.

ACORN SQUASH do.

Together with a complete assortment of Fresh Garden Seeds, including those raised by the United Society of Shakers at New Lebanon, N. Y.

I. I. HITCHCOCK.

PUBLIC SALE OF DURHAM SHORTHORN-ED CATTLE AND HIGHLY IMPROVED SHEEP.

Will be sold on Wednesday, 29th day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd, the highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEIFERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young Lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand.

April 5,—St

DAVID MEADE, Administrator.

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at 75 cents per bushel.

I. I. HITCHCOCK,

American Farmer Office and Seed Store.

SINCLAIR AND MOORE'S NURSERY.

The Proprietors are about to clear a part of the ground, now occupied with white Mulberry Trees, in order to plant other articles, to which the exposure is peculiarly adapted, in consequence will dispose of them at very reduced prices;—after these are sold the regular price will be ten dollars per hundred for trees eight to ten feet high.

They also offer for sale at reduced prices an extensive assortment of Ornamental Trees and Shrubs, fifty kinds of hardy Rose Bushes, (among which is the much admired Greville,) double Altheas, Honeysuckles, Corcorus, Lilac, Snowberry and Buffalo Berry Trees, Chinese Alanthus, white flowering Horsechestnut, and silver leaved Maple, all of large size, (the latter is a beautiful shade tree,) large red and white Dutch Currant, red and white Antwerp and other Raspberry Bushes, Strawberry Plants assorted, (large plants raised carefully for sale,) white and black Walnut, Quinces assorted, Peach Trees, a large stock of very superior kinds, Apple, Plum, Pear, Cherry and Nectarine Trees; Grape Plants and Cuttings of several varieties, Asparagus and Hop Roots, and Thorns for hedging.

Apply at the Nursery, or at their store, corner of Pratt and Light streets. Feb. 22.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythies, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street.

Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—We have not the slightest alteration to make in our quotations of country produce, except a trifling one in corn. The wagon price of Howard street flour remains at \$5.25. The receipts of grain are quite limited, and fall considerably short of the demand, which will account for the price of wheat being rather disproportionate to that of flour.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 5.00. The inspections of the week comprise 854 hhds. Md.; and 122 hhds. Ohio—total 976 hhds.

FLOUR—best white wheat family, \$6.75 a 7.25; super Howard-street, 5.37½ a 5.50; city mills, 5.50 a 5.75; city mills extra 5.50 a 5.75;—CORN MEAL bbl. 3 62½;—GRAIN, best red wheat, 1.20 a 1.25; white do 1.30 a 1.35;—CORN, white, 62 a 63, yellow, 65 a 66;—Rye, 75 a 77;—OATS, 37½ a 41.—BEANS, 75 a 80.—PEAS, 65 a 70.—CLOVER-SEED 8.00 a —.—TIMOTHY, — a —.—ORCHARD GRASS 3.00 a —.—Tall Meadow Oat Grass 2.00 a 2.50.—Herd's, — a —.—Lucerne — a 37½ lb.—BARLEY,—FLAXSEED 1.50 a 1.62.—COTTON, Va. 11 a 13.—Lou. 12 a 13½.—Alab. 11½ a 13.—Tenn. 11a 12; N. Car. 11½ a 12; Upland 11 a 12½.—Whiskey, hhds. 1st p. 29½ a —; in hhls. 31 a 32.—WOOL,—Washed, Prime or Saxony Fleece 45 a 50; American Full Blood, 38 a 42; three quarters do. 33 a 38; half do. 30 a 33; quarter do. 28 a 30; common 25 a 28. Unwashed, Prime or Saxony Fleece, 25 a 30; American Full Blood, 22 a 25; three quarters do. 20 a 22; half do. 18 a 20; quarter do 16 a 18; common, 16 a 18. Hemp, Russia, ton, \$195 a 205; Country, dew-rotted, 6 a 7c. lb. water-rotted, 7 a 8c.—Feathers, 37 a 37½.—Plaster Paris, per ton, 4 25 a — ground, 1.50 a — bbl. Iron, gray pig for foundries per ton 33.00 a —; high pig for forges, per ton, 28.00 a 30.00; bar Sus. per ton, 75.00 a 85.00.—Prime Beef on the hoof, 5.50 a 6.25.—Oak wood, 3.00 a 3.25; Hickory, 4 50 a 5.00; Pine, 2.25.

CONTENTS OF THIS NUMBER.

Editorial; The Drought; Dahlias—The Compass Plant—Wash for Fruit Trees—Locust—Account of an Agricultural Excursion, made into the South of Georgia, in the Winter of 1832, by John D. Legare, Editor of the Southern Agriculturist—On Draining; its Advantages and Practicability—On Leached Ashes as a Manure—Essay on Vegetable Physiology, read before the Buffalo Lyceum, New York, by Lewis F. Allen; Vegetable Life; Vitality of Seeds; Germinating Principle; Root; Heart; Albumen; Bark; Leaf; Food of Plants, how converted into Vegetable Nourishment; Selection, Removal and Planting of Trees; General Remarks—On Cutting Down and Cleaning Up the Margins of Rivers and Creeks, and Straightening Creeks and Branches—Prices Current of Country Produce in the New York and Baltimore Markets—Advertisements.

The American Farmer,

Edited by GIDION B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum: due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect AT THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

☞ DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "I. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, MAY 24, 1833.

VINE DRESSERS, will pay attention to the advertisement of Mr. Henderson, on our last page. If the extent of the vineyard be considered sufficient for a beginning, (about two acres,) we think, all other circumstances will be found perfectly satisfactory to one skilled as a vigneron. The situation is very healthy; and the location one of the most desirable that our country affords, for the economical and pleasant maintenance of a family.

FARMERS AND OFFICE.—There is so much good sense in the following article, written by Judge Buel, of Albany, that, though not as practical as we could desire for our editorial page, we have thought our readers would be pleased with it. No man is a better judge than Judge Buel, of the evil tendency of a thirst for office, especially among farmers.

HINTS TO FARMERS.—Offices are created for the public, not for the incumbents. They nevertheless constitute fruitful rewards to merit; and, when spontaneously conferred, are among the highest honors that a free people can bestow. To *deserve* them is worthy of your ambition; but to *depend* upon them, as a means of livelihood, would be unreasonable and unwise, if not dangerous. A thirst for office is almost as bad as a thirst for rum. The more either are indulged, the more craving they become. Every repetition of the potion but begets new desires, until, finally, the passion, in one case, terminates in *delirium tremens*, and, in the other, in *delirium cordidum*. I have known many a worthy man ruined in his usefulness and in his fortune, by this latter disease, and ultimately terminate his career under the complicated horrors of both maladies.

In selecting your public agents, adopt the same caution that prudence would suggest in your private affairs: choose those who are acquainted with the business in which you mean to employ them,—who know your wishes and your interests,—who have an established reputation for integrity, and who have shown an ability to manage a public trust, by having conducted creditably and successfully their private affairs. Such men possess civil virtues, and merit civil rewards. But distrust the man who reiterates his importunities for your vote or your influence, as wanting either good habits or good principles. The first should render him independent of public aid, and the last should make him ashamed to ask for it.

Are we then to reject, as the bane of our happiness, the honors and emoluments of office? Not accept them, when proffered, as a mandate of duty, not as a source of wealth; as a compliment to your merit, and as the requital of an obligation which you owe to society. Accepted in this spirit the duties will not seem onerous, nor the emoluments worthy your exclusive regard. And when you have enjoyed the honors, and fulfilled the duties, abandon neither your politics nor your religion, because your fellow-citizens happen to discover in your neighbor qualities and merits equal or superior to your own. The spirit of a free government forbids monopoly. Whether they impose a duty, or confer honor or profit, offices should be shared by those who are capable and worthy; and I do not know of a more salutary provision which would be engrafted on our constitution, than that which has been thrice forcibly recommended by our illustrious President, to limit the tenure of office to some definite period of time.

I will also close this number with the history of a schoolmate;—*Job Allerton*, commenced life under the most flattering auspices. His farm was a pattern of neatness—fields well cultivated, cattle in fine order, and fences and buildings in good repair. Job owed no man, and had accumulated a fine sum at in-

terest. His children were growing up under their parents example in habits of industry, and promised to become respectable in society. Every thing thrived under his care, and he was pointed to by all as the best farmer in the town of S. His good qualities, and the influence which these procured him, at length brought him into political notice, and he became a successful candidate, very much against his will, for the Assembly. He returned from Albany in the spring, with some new notions, but the habits of the farmer still predominated. To a second nomination Job had less objection, nay, he secretly intrigued for it; for he thought, as he remarked, he was then qualified to do some good. The second triumph, and the consequence it gave him at the dinners and parties in the renowned capital turned his head, and he came home quite an altered man. It was no longer "Come, boys," with him. Politics engrossed his whole attention. He became a standing candidate for every office that presented; and was in succession—sheriff, senator and member of congress.

In the mean time the farm began to show the absence of the master; the fences were prostrate, the cattle neglected, and the buildings verging to ruin. The boys too, as boys ever will, aped the father, began to strut the gentleman, and to look up for office and dignities. As industry departed, prodigality entered, and soon wasted the frugal earnings of former years. At length the illusion vanished. Allerton found himself deeply in debt, without means and without office, with an indolent, extravagant family to support. Offices had ruined him. In his distress he mustered resolution to do what hundreds have failed to do, and who have done worse. With the wreck of a former competence, he pulled up stakes, and leaving behind him his official habits and official pride, fled to the wilds of Indiana, where I am happy to say, he has resumed again the habiliments of the farmer, and is profiting by the lessons of experience.

Who is there that among his acquaintance does not recognize a Job Allerton? B.

SPLENDID FLOWER.—The Greenock (Scotland) Advertiser, gives the following description of the *Cinnamabale*: "The plant is a native of the East Indies, and measures one foot eight inches round the stem; leaves from three to four feet long, and six inches broad; flower-stalk three feet long; the flower is one foot six inches in circumference; umbel flowers at the top one foot eight inches in diameter; the flower changes from a crimson to a beautiful pink color, which surpasses that magnificent exotic, the *Doronic excelsa*, which the late Mr. Henderson, gardener at Woodhall, was so successful in flowering."

ENGLISH WEATHER AND GARDENING.—The London correspondent of the Auburn Free Press, mentions as a remarkable circumstance, that on the evening of January 6th, the moon was distinctly visible for several hours, and thousands sat up to enjoy the sight. The weather has been extremely mild, till within a few days. On Christmas day wild strawberries were picked in Uxbridge, and on New Year's eve flowers were gathered in a spot as little sheltered as any in Falmouth. I have just seen a description of the manner of cultivating the land here, which may be interesting to you. In the immediate vicinity of London are 10,000 acres of land used for the growth of what is called garden stuffs—2,000 of which are cultivated by the spade. "Shortly after Christmas when the weather is open, radishes, spinach, onions and all other seed crops are sown, and as soon afterwards as the season will permit, which is generally in February, the same ground is planted with cauliflowers from the frames, as thick as if no other crop then had possession of the ground. The radishes, &c. are soon sent to market, and when the cauliflowers are so far advanced as to be earthed up, sugar loaf cabbages are planted; when these are mar-

keted, the stalks are taken up, the ground cleared and planted with endive and celery. The average produce of these gardens is supposed to amount to \$888 00 annually, per acre." The annual produce of all the garden ground cultivated to supply the London markets was estimated by Mr. Middleton at \$2,853 800 which with \$1,776,000 00 produced by the fruit gardener, makes a total of four millions, six hundred and thirty-nine thousand, eight hundred dollars, for the consumption of the metropolis in fruits and vegetables only.

TOBACCO—INQUIRY.

MR. SMITH: May 16, 1833.

A Virginian planter, would be greatly obliged if he could obtain some information through your valuable paper, on the subject of the tobacco culture, as pursued in Prince George's county, Maryland, embracing the raising of the plants, with all the process of cultivation, curing and pressing.

(From the New England Farmer.)

REMEDY AGAINST THE BEE-MOTH.

FRIEND FESSENDEN: Mansfield, 6th mo. 4th, 1833.

There has been much said concerning keeping the grub worm (so called) from the bee hive. The mischief is done by flying insects, called millers, which visit bee-hives in the autumn. I have not marked the time particularly; but according to my observations, it is but a few days, in which they make their ravages. These millers deposit their eggs in the hive. The eggs hatch and become worms, which destroy honey and swarms. The millers come between sunset and dark, or after it becomes somewhat dark, and the time in the evening in which they make their efforts, is not more than half an hour. This being the case, I took my small earth furnace and placed it near the bee hives, in order to attract the millers to the fire, which I made in it. But I found that it had the contrary effect. It dispelled them. I have done this two or three years with success, and have had none of the grub worms in my bee hives since. More particularly—set the furnace, say two yards from the hives, and make in it a fire of shavings or any light fuel, so that the light may shine on the hives. If the wind should blow the smoke on the hives too much, set the furnace farther off; but previous to all this let the mouths or doors of the hives be stopped except on the front where the fire shines.

This is of considerable consequence in economy, and I wish those who keep bees to prove the experiment; and when I shall hear from them, I shall say more about bees—but one thing at a time.

LEWEL GROVER.

ROSES—Lovers of these, the queen of all flowers, would be gratified by taking a pleasant ride of three miles east of the city, by the Bellair road, to Sinclair and Moore's Nursery, where they may have an opportunity of seeing a very large collection of roses (especially the hardy kinds) now in full bloom, affording the best opportunity of making selections against the transplanting season. The other departments of their Nursery, seed raising, and farm, would also be amusing and interesting at this pleasant growing season, where large crops of the following vegetable seeds are now ripening, the purity of which may now be examined: Large white flat and purple top turnip, parsnip, carrot, beet, radish, rape, ruta baga, spinach, onion, &c.

S. & M.

FOREIGN MARKETS.

LIVERPOOL, April 5.

Cotton—Dealers and spinners are yet holding back a little in fear of blowing up prices, and this has caused holders to offer their stocks more freely. The sales are near 3,000 bags, steady prices, consisting mainly of American descriptions, ranging from 7 to 7½d; except 100 Bahias at 8½ to 9d; 25 Surats 4 5-8 to 5½d; and 50 Madras 6½ per lb.

AGRICULTURE.

HORIZONTAL PLOUGHING, AND HILLSIDE PLOUGHS,
AGAIN.

MR. SMITH: — Virginia, May 7, 1833.

From the tone of your editorial remarks, in reply to certain queries on the subject of "horizontal ploughing, and hillside ploughs," which appeared in your eighth number, I am led to believe, that you have misapprehended either the purpose or meaning of the letter which conveyed them. That letter was certainly written with no view of detracting from the just merits of any one—and though penned in haste, I cannot but think, on a second reading, that it carries on its face the design (if there be one, separate from the simple desire of being informed as to the history of a much valued improvement) of bestowing honor where it is properly due.

Neither is this a question of *gratitude*,—as we both probably concur as to the superiority of the mode and instrument of tillage, introduced by Gov. Randolph, over those before used for the same purpose,—and I have but to repeat the remark of my former letter, "that if he was the original inventor of them, he merited the thanks of the whole agricultural community, and perhaps not the less if he *merely* introduced them, and improved the construction of the latter" so as to render it more valuable.

We certainly, however, differ as to some general views, and one or two minor points; which latter, in truth, were the *gist* of my queries. I did not suppose myself to be in possession of all the facts on the subject, or I should scarcely have withdrawn your attention from matters of greater importance, to gratify, what is, perhaps, an idle curiosity. I will confess, however, that my former impressions were somewhat different from your own, as it respects the history of this matter, and will present some of the authorities which induced them. It was unknown to me, that Columella, had recommended the practice in question, and the information is, in so far, an answer to my former communication—inasmuch as it traces the theory, at least, to a higher point, than I had before read of. I had often admired this plan of culture, and reflected with pleasure on the agency which it has already had in repairing the desolation caused in some parts of this state by the opposite mode. Foreseeing yet greater benefits, as I thought, from the introduction of a farther improvement, I felt grateful to the individual, who, as I then supposed, was its first inventor, and who certainly first impelled the minds of American farmers in this direction. It was not unnatural, then, that my attention should be arrested by such a passage as the following, in a work which was in my possession. As it is the only copy of it which I have seen, and as I do not find it in London's catalogue of agricultural writers, I will add the title, so that you, or some of your readers, may verify the extract, should you meet with it. It is a small duodecimo volume, and purports to be written by a lawyer, who had deserted the bar, for the more profitable employment of farming. The author professes to have *practised* the precepts of his book which embodies in a lively and perspicuous style, the then existing improvements of English agriculture, and is not the only tribute of a retired lawyer, to the nobler profession.* Its title is as follows: "A new system of agriculture, or a plain, easy, and demonstrative method of speedily growing rich; proving by undeniable arguments, that every landowner in England, may advance his estate to a double value, in the space of one year's time. Together, with several very curious instructions, how to feed oxen, cows, and sheep, to much greater profit than has ever been known in England." London, printed for A. Miller, 1755. This *portico* to his structure is rather in the style of that day, but like other

porticos it might serve to attract attention to that, of which it was the mere appendage. As the mottoes are somewhat quaint, they also are subjoined.

"The only gentleman-like way of growing rich, is by the art of husbandry. All other professions have something in them of the mean and subservient.— This alone is *free*, and noble; and the wealth thus gotten may alone be said to be of a man's own creating."

Gooze of Husbandry.

"Male agitur cum Domino, quem riticus docet."

Cato de Agricultura.

This latter maxim is not inapplicable to many of our southern farmers, and their overseers, as some of them have felt to their cost. And possibly a sentiment somewhat analogous to the former, being deeply seated in the heart of the agriculturist, may have aggravated the tariff controversy.

Here follows the extract taken from near the close of the work:

"I can't introduce a very useful observation in a more proper place than this; and that is, *when the land you are to plough is the side of a very steep hill*, as it often is, 'tis down-right madness to proceed as most countrymen do, by ploughing directly up and down the steep. In this case, 'tis pity the driver is not in the place of his team; he would then, perhaps, discover that *'twould be the wisest way to plough across the hill*, by which means the cattle would not only draw with the same ease, as if they worked on plain ground, but the furrows, lying athwart, would prevent the rains from washing down the fatness of the soil, with every flood; a misfortune to which at present, all the lands are yearly liable, and often ruined and impoverished by it."

This passage certainly contains the idea in question, and pithily describes the barbarity (in more senses than one) of its neglect. Nor does it seem to be announced as any new discovery. But as this authority is in a measure unknown, I will add further, that it is not necessary to go abroad, or to obscure authors for testimony. A friend, to whom I had spoken of the above passage, informed me that he had heard the late Col. Taylor, of Caroline, in conversation on this subject, mention that horizontal ploughing had been practised in a particular district of Scotland, for more than a century. Since receiving your paper to-day, I have looked into "Arator," and find in the number on ploughing, a remark, (the which, if I had before known, I do not think I should have troubled you with my former queries.) It is this, "deep ploughing combined with enclosing, &c. vastly obstructs the formation of gullies in hilly lands even if fallowed with a level surface. But such lands will admit of narrow ridges as well as level, by a degree of skill and attention so easily attainable, that I observe it to have existed in Scotland above a century past, under a state of agriculture, otherwise execrable, and among the ignorant highlanders. It is effected by carrying the ridges horizontally in such inflections as the hilliness of the ground may require, curved or zigzag preserving their breadth." Farther on, he observes: "this classic system of agriculture has been *introduced* into Virginia, by a gentleman of Albemarle, in a style completely adapted to the state of the country," &c.

Here then is additional, and perhaps sufficient confirmation of my former impression, that the idea was not *new*, even if original with Gov. Randolph. It scarcely appears too that "the theory although eighteen hundred years old, had been passed by as unworthy of attention during the whole of that time, or that while adverted to (as we have seen) by writers, it failed to be reduced to practice."

In relation to the other topic, one of your remarks seems somewhat equivocal, you say that horizontal ploughing "was most probably practised by the Romans, and of course, a hillside plough of some sort was used by them." Rather a "non sequitur" I suppose, since thousands practise this mode in our country without using the hillside plough, properly so called, unless the common implements be dubbed with

this title while ploughing the steep, and anon, receives another when it reaches the plain. The principle on which this instrument is constructed, (and which I mentioned as having been suggested before,) is that of the double mold-board which is made to perform a semi revolution on the single axis to which they are both fixed, so as always to present one of them towards the base of the hill.

My authority for this is another English work, "Forbes' Agriculture," which though, with the one first above mentioned, left out of London's catalogue of English writers on this subject, appears to have been cited by one of the Agricultural journals of this state, (vide Virginia Farmer, vol. i. Nos. 17 and 18.)

In the American Farmer, vol. ii. p. 320, Mr. Sinclair, of your city, speaks of these instruments as having been *originally invented* by Gov. Randolph, and much improved by himself. By this, and other evidence, others, with myself, thought that nothing of the kind had ever been known before, not only in America, but, at least, in that country with which we have had most intercourse, and from whom we have derived most knowledge on this subject. Here follows, then, an extract from Forbes, p. 638. It is the description of a plough, of which, two figures are given, but as the other parts of it are unnecessary to the illustration, I shall present the second alone.

"This is a turn-wright, or turnrest, and by some called a turn-ridge plough. It turns the furrows all one way, laying the land level, without ridges, or parting furrows. And in sideling or sloping grounds, where the descent is too great for the cattle to draw the plough up and down the side of a hill, and too steep to turn the furrows up against it, this plough performs the tillage very well; the cattle *drawing it across the descent*, (qu. is not this horizontal ploughing,) it turns all the furrows downwards, or with the descent. It differs from the swing-plough in the mold-boards, which in this plough are *double and moveable*. The mold-boards *bc* and *de* are fastened together at their foresides, by joints or hinges as at *n*. When the furrow is to be turned to the right, the mold-boards stand in the manner represented in the figure. And when the plough returns, the mold-board *bc*, should be drawn up to the beam; and *de* then becomes the mold-board, being set out on the left side of the plough, by the wooden pins *cd* and *be*, which connect the two mold-boards, and pass through the sheet at *d* and at *e*. The pins should be drove tight into the holes in the mold-boards, but to slip easily through the sheet of the plough; so that either mold-board may be set out by the hand, or a small blow or two with the hammer. This is a very ready way of shifting the mold-boards; and the plough performs very well without wheels. The share has no fin, and is broad or chisel-pointed at *s*.

"To guard the joints and foremost ends of the mold-boards, a small bar of iron, *om*, may be fixed in the beam, thickest at the back next the sheet, and thinner towards the foreside. This bar will cut the earth, and open an easy passage for the mold-boards, and strengthen the plough."

You can judge whether there is any thing in this quotation that bears on the point before us. It may be said, indeed, that "that individual should be regarded as the true author of these improvements, who blessed our country with them, and we care not where he obtained the idea." This again appears somewhat inconclusive, or the lucky wight, who first changed or introduced the drill husbandry into the United States, might dispossess old Tull of what have heretofore been regarded his rightful honors. And although we may not care where the idea of a useful invention comes from, when we have the thing itself, may not a little curiosity about the matter be sometimes par-

* Tull, the father of English agriculture, was in early life a barrister.

[*We have thought it unadvisable to incur the expense of the engraving referred to. The object of the writer is certainly accomplished without the aid of the engraving.—Ed. Am. Far.]

done, although there be no apparent *utility* in the inquiry, or even if it savors of the antiquarian spirit?

The above extracts are given, not from a pedantic motive, but simply, because they fell in my way, and bore no internal evidence of their being original speculations, and the queries were submitted in hope of ascertaining whether any thing earlier had been known with respects to these subjects.

Grateful too as we should all feel to Gov. Randolph for what he actually *did*, why not discriminate the precise object and motive of it. It is very possible that he, although a scientific and classical man, may have hit on the idea in the course of his own reflections, or the hint may have been suggested in the course of his multilarious reading—afterwards forgotten—and subsequently risen to his mind's eye, unconnected with the name of the author from whom he received it, after having lain dormant for a long period in his memory. Or, perhaps, (and this is the most charitable supposition,) the necessity of doing something to remedy the appalling evils of the opposite system, may have forced his mind into the path which led to the happy thought. But an invention, made by two or three persons, unconnected with each other, and neither of whom has in any way communicated his ideas to the others, is not the exclusive property of any of them. Just as it is said that the method of fluxions was invented by Leibnitz and Sir Isaac Newton, almost simultaneously—and yet no one doubts the high powers of either—such cases being by no means rare in the history of art.

But to descend from these useless topics to something more practical.—I had intended to add something on the improvements which *have been* substituted for *exact* horizontal ploughing in this state—but really, you have dismissed my fourth query, in a style so very summary and cavalier, that you must have thought it either a quiz, or a ludicrous mistake. I assure, Mr. Editor, that it was neither the one or the other, although somewhat enigmatical from its haste. But my communication is already so extended, that I will not trespass further on your columns, than to add that the question is not as to the superiority of exact horizontal ploughing to the common; but whether, in some climates and soils, it has not been found so far to fail of its purpose as to produce great and lasting injury, which might be avoided by a slight change in the mode. If your readers are not wearied with the subject, it may be resumed at some future period by
A VIRGINIAN.

(From the Southern Agriculturist.)

ANSWERS TO QUERIES ON THE CULTURE OF RICE. MR. EDITOR:

Experience has convinced me that there can be no uniformity in the mode of cultivating rice, even on the same plantation, for a consecutive series of years; system there must be, but that must yield to the tyranny of circumstances and seasons. The principal thing is to understand the peculiarities of the soil, its advantages as to flowing and drainage, and the grasses which infest it most, and whether of a character to be managed by water or the hoe. This view of the case, and my wish to aid your valuable efforts, must plead an excuse for the indecisive and somewhat vague answers returned you by
COLUMELLA.

Query 1. What preparation is given the land prior to planting, is it broken up by the plough or hoe?

Answer. The best preparation of land prior to planting, depends upon the quality of the soil. If friable, light and rich, the hoe is the best implement for turning it; if of a clay texture and stubborn, the plough is preferable, and worked as deep as practicable, since the luxuriance of the growth depends much on the depth or tilth of the cultivation. On lands of the first description, chopping is the next process,

and is enough. On the latter chopping and harrowing are both advisable, though the latter is alone used at times for expedition. I would remark that in the cultivation of stiff clay land, the preparation for the reception of the seed is one of the most important points.

After the land has been digged or ploughed, if clay, it is very noxious to flow it, as it destroys the action of the frost, which would pulverize and improve it for planting. Lighter lands may be treated differently, and it is my opinion, that all lands are enriched even by the winter flowing, though the banks and ditches are apt to be injured.

2. When is planting commenced?

1. The time to commence planting depends much on the warmth or coldness of the soil, varying from the 20th of March to the 10th of April, but I think the safest is to begin about the 1st of April.

3. Are the seeds selected, and by what are they judged. Is there any preference to be given to seed obtained from the North or South, or from river or swamp-land—how often is the seed changed—how is seed-rice best obtained?

1. The best seed is that which is freest from red, and that grown on inland swamp is generally the best, both as to the above requisite, and in consequence of the grain being larger and more pearly. I have seen seed-rice with not a grain of red in a quart.

4. How near are the rows, and what quantity of seed is used per acre?

1. If the land is in fine order, I prefer the near trenches, i. e. fourteen inches and string planting, but in clay lands, which are always more or less lumpy, sixteen inches is the best distance; and the seed should be scattered in a trench about four inches wide at the bottom. In light alluvial land, a bushel and a half is the best quantity per acre. In clay lands, which of course, cannot tiller as much, two bushels per acre. The hoe trenching is preferable on account of neatness as to looks, and is also better than the plough trenching, inasmuch, as it is not so deep, and I prefer the light trench, from the impression, that rice tillers better the more it is planted on the surface, and also, because it has more loose soil below to sustain it, which is all important in stiff soils.

5. How are the seeds sown, in open trenches or on the string, do you cover or flow without?

1. In sowing, I never task the sowers, deeming it too important a part of the process for haste, I think, however, they do about one and three-quarters of an acre. With respect to the covering with water instead of dirt, termed "the open trench planting," it answers perfectly well on light lands, but cannot possibly be substituted for the old mode in clay soils; as the rice is never sufficiently covered with mud to ensure its safety, even after it has taken root and the water been drawn off.

6. Do you use the point-flow, and what are the advantages?

1. I have not used, but seen much of the point-flow. Where the land is grassy, (with the exceptions of joint and goose grasses,) the soil of a clay texture, and the land level, the point-flow for about two days is very advantageous; but the water must not be deep enough to spindle the rice, nor used after the hot weather in May sets in, as the water is apt to heat and scald the rice. It is a flow which requires great judgment, and therefore, cannot be recommended generally.

8. How often do you hoe before you put on the water? How long is the water kept on?

1. I endeavor to hoe twice before I put on the long-flow, as the rice, though apparently backened, in reality is acquiring vigorous roots, to derive the full benefit of the water, which unless to assist in mastering the grass, should not be kept on longer than ten days, as it makes the period between the long-flow and the joint flow too short. It frequently happens, however, where the rice is combating

grasses which the water can destroy, such as water-crab, and many others, which it can backen if it cannot destroy, or run them up so as to separate them from the rice; that the water should be put on before the rice has been hoed at all, as rice is more injured by the enemy of grass, than from any other cause.

9. Has the plough ever been used whilst the crop was growing?

1. Though very unusual, I have used a plough constructed for the purpose, to break up the alleys between the rice, when about ten inches high. It made a fine preparation for an immediately subsequent hoeing, but the trouble of clearing the lumps from the rice, and the new mode of near trenches, made me abandon it.

10. What is the after culture of the crop—what is the latest period in reference to the forwardness of the rice, at which the hoe might be used advantageously?

1. When the long-flow is drawn off, the rice should be kept as dry as possible, hoed, but not as deep as the second hoeing, picked clean and allowed to recover the dry growth, until the first joint appears, when the water should again be put on. I would on no account hoe rice as late as the period for it to joint, as it stands then in need of all the roots it has put forth. If grassy, it should be hand picked. I would, also, remark, that the water should be frequently changed, or purified with fresh water.

11. When ought the water to be turned off previous to cutting the rice?

1. The water should be drawn off preparatory to the harvest, about ten days, but planters, in general, from the apprehension of gales, keep it on longer.

12. How is the best period for cutting rice ascertained?

1. With respect to the time of cutting, I think it best when eight or ten grain, at the foot of the ear are unmaturing. They will harden after the rice is harvested, and much waste will be avoided.

(From the Southern Agriculturist.)

ON THE CULTURE OF RICE ON HIGH LAND, CORN AND PEAS.

Newbern, N. C. April 7, 1833.

Dear Sir,—Yours, of the 27th of Marc, has before me. I have made two small crops of rice as an experiment. The first crop was planted in drills three feet apart upon high, dry, sandy land that had been cultivated for a number of years in corn and cotton, and would have produced in corn, about ten bushels the acre. The rice was sowed in the drills at about the rate of a half bushel to the acre, during the middle of April, and covered lightly. It was afterwards cultivated with the plough and hoe in a similar manner as cotton. The season during its growth was favorable. When threshed and well fanned it yielded thirty bushels to the acre, and was disposed of in its rough state at forty cents a bushel. The second crop (this is my last one) was planted about the same time of the year as the first one, and about as thick in the drills upon low, wet land, just cleared. It did not grow so thrifty as the first crop upon high land, owing probably to the land being new and trashy. Some parts of it fired and came to naught. Upon the whole since it has been gathered and cleaned, I think it has yielded about equal to the first crop. Circumstances have prevented my measuring it. This crop I intend to clean, having erected a little machinery for the purpose. It is of the golden straw variety. I have, no doubt, but that this low land when properly reclaimed will yield sixty bushels to the acre. Low wet lands here called "savannahs," with clay foundations, have yielded this quantity. The crop requires about the same quantity of labor to make it as cotton. I have never planted it among corn, but have frequently seen it so planted. In a dry season upon high sandy land, I think it would fail. So prolific is it in breeding worms, that corn

planted in the soil immediately after a crop of it, is sure to be eaten by them while young. The rice made here is heavier by three pounds in the bushel than yours, owing to our more northern climate.

In cultivating corn upon sandy land, I commence by breaking the soil intended for it, in February, not deep. Sandy land should never be ploughed deeply. When broken it is crossed at intersections of six feet square, and on the first of April planted with three grains in each hill. Afterwards if there are any missing hills they are replanted. The field is ploughed over every fortnight, and hoed about the hills at least twice during its growth, and oftener if convenient. A hoeing at the time of thinning it, to two stalks in a hill, is indispensable, as is also a hoeing at the period of laying it by, to make a good crop. Four or five ploughings make the crop. My crop the past season averaged to the acre, three and one-eighth of a barrel of five bushels each.

In the centre of the squares of corn we plant, about the tenth of June, a hill of cow-peas, (ten or twelve peas.) If the land is freshly cleared, they yield a handsome return. If old, they yield but little. These we cultivate by simply keeping the grass from them. We do not hill them. We find them good food for both man and beast, and they ameliorate the soil by their shade. Sometimes they are sowed, and just before they blossom are ploughed into the soil to enrich it, with a very good effect. They are a valuable addition to the corn crop. Land much worn may be made to produce them again by manuring it. They do not look so well upon the table, owing to their color; but boiled until soft, with a piece of bacon, they are preferable to all the other species of the peas, except, perhaps, the garden peas while young. They are more productive than any other species, and have more gluten.

I have this spring carted and spread upon twenty-five acres of land, one thousand six hundred loads of manure, (three mules in a cart.) When not otherwise engaged, all my force is employed in bringing trash from the woods and throwing it into the horse stable and cowpens to make manure. By this means, in the course of the year, there is amassed a respectable supply to enrich the poorer spots of the farm, and it does enrich them wonderfully. By this process, these twenty-five acres have been brought from ten bushels to thirty, in two years, and my desire is to bring them to fifty.

Manuring is a partial remedy for emigration, the spirit of which is so prevalent here, that vast numbers leave us for Alabama, Tennessee, &c. where they expect to find richer soils. Probably they may, but when they come to count the cost of a breaking up and a removal, and in getting well settled again; many of them have gained but little, if any thing. Nor are they ever afterwards satisfied in having exiled themselves from their father land. And what is money to a dissatisfied spirit? And if a struggle against difficulty is a virtue, it is virtuous to enrich a poor soil, and probably in many cases, it is also the best economy. Of these matters every one assumes the right to judge and decide for himself. May they do so with advantage to themselves. In the interim, North Carolina is depopulating, and must, finally, be tenanted by her primitive occupants—beasts and Indians. Thus changes the world!

Respectfully, GEORGE WILSON.

NEW POTATO.

We were shown last Saturday a quantity of new potatoes just taken from the ground. They were planted late last fall and by the assistance of a deep coat of manure and good, warm soil, they vegetated during the winter and grew so large as to be fit for eating on the last day of March. It seems to us there might be some expedient contrived by which vegetables can be had earlier in the season, if not a considerable portion of the year round.—*Northampton Courier.*

(From the New England Farmer.)

CULTURE OF INDIAN CORN.

MR. FESSENDEN: Northampton, April, 1833.

Sir,—If you think the following account of some experiments relative to planting corn, worth a place in your Journal, it is at your service.

For some years, I have planted my corn thicker than has been thought a suitable distance, by farmers, generally, in this section of the country; and to me it has appeared decidedly to increase the crop. But as that was a matter of opinion, I made a little experiment; rather, however, to remove the doubts of others, than any of my own, on the subject.

I will premise by stating that the ground on which the first experiment was made, was a sandy loam, rather cold, and though naturally pretty good, was so run down by neglect and severe cropping, that in 1831, it gave probably less than half a ton to the acre, of poor sour hay, worth little else than to throw into the barn-yard for litter and manure. In May, 1832, it was ploughed, and about twenty cart-buck loads per acre, of a compost, (which was made, one load of manure, to two of meadow-mud or good soil, and piled up in layers the previous autumn,) were spread and harrowed in on the furrows.

The situation was one much subject to early frosts, and the crop probably suffered a diminution of about one-fourth, by that which occurred in September, and by which nearly all the leaves were killed, while the stalks pretty generally remained fresh and green.—The effect of this frost, was very similar to what I should have expected, from topping the stalks at that time. The corn was full in the milk, and the process of filling out, ceased entirely where the leaves were all killed; and where nothing more than the leaves were killed, the corn dried or shrivelled up without rotting.

I believe the farmers here, usually, give fifteen to eighteen feet, and I have seen some lots where twenty feet of ground were given to a hill.

In 1831, I gave twelve feet to a hill, and in 1832, it was my intention to give, generally, about ten feet, or to plant the hills a little more than three feet distant each way. The ground being prepared as above stated, and all treated alike, there seemed to be very little difficulty in making an experiment that might prove satisfactory, in determining whether I was giving the hills room enough or not. Accordingly about half a dozen rows were planted, at about four and a half feet from hill to hill, and as many more rows next adjoining were planted at about two and a half feet from hill to hill in the rows. The rows all being three feet apart.

All were alike until harvest, which was about the 10th of November, when for the sake of making as little trouble as was consistent with a fair result, I fixed on two of the rows, which were standing side by side, and which I shall call No. 1. and No. 2; as being sufficient for my purpose.

In No. 1 there were twenty two hills on one hundred feet in length, and the rows each side being three feet distant; it gave an average of 13.58 square feet of surface to a hill, or three thousand one hundred and ninety-seven hills per acre.

In No. 2 there were thirty seven hills on one hundred feet in length, and being the same width as No. 1, it gave an average of eight and one-ninth square feet of surface to a hill or five thousand three hundred and seventy-two hills per acre.

The corn was husked in the field, and carefully weighed, and seventy-five pounds of ears (the usual quantity) allowed to produce a bushel of shelled corn. No. 1 contained seventy-seven hills and gave fifty-one and three-quarter pounds of ears, equal to ten ounces and twelve grains per hill, or twenty-eight bushels and forty eight pounds per acre. No. 2 contained one hundred and thirty-two hills and gave seventy-five pounds ears, equal to nine ounces and a half grains per hill, or forty bushels and forty-four

pounds per acre. Making (in this case) eleven bushels and seventy-one pounds per acre in favor of the thick planting. It will be perceived that while the hills in No. 1 gained, individually, nearly twenty per cent. of those in No. 2; which by the way was very much calculated to mislead me as to the real result, if no other method than guessing has been adopted, they collectively, by the acre, made an entire loss of about thirty per cent.

The difference was greater than I had anticipated, and perhaps much greater than it would have been on a different soil. Therefore, I have given you some particulars relative to the soil, and management in this case, in the hope, that some of your readers, will make comparative experiments, in other kinds of soil, and give the result through the columns of the N. E. Farmer; that thus by making common stock of our experience, we may be able to take, at least, one important step, in the cultivation of this most valuable crop, independent of the old method of guessing at it.

I have given the data from which the estimates were made, so that if any inaccuracy has been admitted, it may be detected.

I also made a small experiment, to test the method proposed by some one (I believe in the N. E. Farmer) of planting the hills much thicker in the rows to prevent the corn sending up suckers, and at the same time giving the space between the rows a much greater width than is usual, for the purpose of freely admitting the rays of the sun. It was on a warm sandy soil, in somewhat better condition than the one above described. The corn suffered some from the drought but not so much from the frost as the preceding. The items were as follows:—No. 1 had thirty-six hills on one hundred feet in length, and the average distance of the rows on either side was three feet three inches, giving each hill 9.4144 square feet, or making four thousand eight hundred and twenty-five hills per acre.

No. 2 (between which and No. 1 there was an intermediate row) had fifty-three hills on one hundred feet in length, and the average distance of the adjoining rows, was four feet three inches, giving 8.2144 square feet to a hill, or five thousand four hundred and thirty-five hills per acre.

In row No. 1 there were ninety-seven hills, the produce of which was sixty-six and a quarter pounds ears, equal to forty-three bushels and seventy-three pounds per acre, allowing as before seventy five pounds for a bushel of shelled corn.

In No. 2 there were one hundred and forty six hills, yielding eighty-eight and a half pounds ears, equal to forty-three bushels sixty-nine pounds per acre.

In this instance it will be seen that the advantage (if there be an advantage) obtained by planting thick in the row, was somewhat more than lost by leaving so large a space between the rows.

On another part of this lot where the ground was rather better, but otherwise, all treated alike, (the manure having been spread on and harrowed in after ploughing,) I measured one row and found the hills occupying 8.19 square feet each, (rows three feet apart,) and yielding fifty-six bushels and thirty-seven pounds per acre.

These experiments would, on the whole, seem to favor the opinion that an equal distance each way is the best method of planting corn; and that on soil similar to what I have described, about nine square feet of surface is sufficient ground for one hill. On a different soil it might want double this quantity—and then again on another soil it might not require as much; comparative experiment is wanted to determine this. It is a subject in which ever New England Farmer is interested, and can be settled only by a careful comparison of the produce of ground planted at different distances; other things being equal.

We want facts.—Raising fifty bushels on an acre where the hills occupy twenty feet of ground each, although we call it a large crop, does not prove that

sixty bushels might not be raised on the same acre, if they occupied but ten feet each.

We want some facts, Mr. Editor, to guide us in raising corn; since the days of the pilgrim, the whole subject in New England has been managed *by guess*ing. Yours, truly,
WM. CLARK, JR.

(From the Maine Farmer.)

CULTURE OF PEAS.

MR. EDITOR:

One great and beneficial object of your useful paper, is to collect and spread abroad experiments, together with the profit and loss of farmers in their several pursuits; I beg leave therefore to make known the following: Mr. John Gilmore, of Monmouth, ploughed a piece of sward land, being one-half of an acre—a light loamy soil. In the spring of 1831, he sowed it with peas and oats, and obtained a good crop without manure. In autumn of 1831, he ploughed it again turning in what grass, &c. had grown on the land. In the spring of 1832 he opened furrows not deep, about 2 feet asunder, and in those furrows he sowed peas of the kind called, marrowfats. This was done as early as the frost had left the surface sufficiently deep to make his furrows; he covered the peas with a hoe. From this half acre having put on no manure, he raised peas enough in the pod to bring him \$17, besides what he used in his family, and he afterwards collected two and a half bushels of dry peas. He therefore realized a profit of \$20, at least from his half acre, without manure and without much labor. Might not some other farmers profit by this experiment by going and doing likewise. Peas are worth more by the bushel for fattening pork than Indian corn, and they are raised without hoeing. I suggest the idea, whether farmers had not better procure the most prolific kinds and raise more of them than they do. If there can be any objections I hope that some of your experienced correspondents will point them out and oblige a
FARMER.

(From the New England Farmer.)

INTRODUCTION OF POTATOES.

MR. FESSENDEN:

Fryburg, April 25, 1833.

I have been a subscriber for your very useful Journal, for about four years, and I highly prize it. Your items of intelligence contain more information of our government affairs, than a basket full of the political papers of the day. I soon get lost in the labyrinth of words, or tired of reading unmeaning sentences, therefore, I read none of them. I have gained much valuable information from the practical and highly scientific correspondence of those gentlemen, who enrich your columns, and also by your notes, on the ancient and modern agriculture of foreign nations, as well as our own.

You seem inclined to enlarge the number of your correspondents. I approach the list with very great diffidence, knowing myself inadequate to the privilege. But, as some very useful discoveries have arisen from small means, I take courage, and will tell you some things that I have noticed in the course of my life, being past the meridian.

Some time since I noticed the introduction of the potato, into one or two towns in the vicinity of Boston, and other information was solicited. Not seeing any from my native town, I will tell you my grandmother's story about their first coming into Wilmington, Massachusetts. I am the only grandson of Captain Samuel Walker, and the only child of Timothy Walker, Esq. of the above town that is living; my grandfather having died before I was born, I know nothing of him; but my honored grandmother lived to the great age of ninety-two years, when I was sixteen years of age, and retained her mental powers to the last unimpaired. About one hundred years, now gone by, she said, that grandfather was at Boston, and found an Irishman just landed from Ireland that want-

ed to work. They agreed, and the Irishman came to Wilmington, and began work, and at meal times he saw no potatoes cooked. He asked grandfather if he had no *potatoes*? He told him "no, he had heard of them, but never had seen any." Patrick said "if they would be letting him go back to the *vessel* he could get some, for they had some on their passage." Grandfather told him he might go, he should be very glad to get some; Patrick went to Boston, seventeen miles, and obtained two only. It being spring of the year he planted them and took good care of them, in the manner in which he was taught to cultivate them in Ireland, till they were grown, when he dug a few of them; and informed grandmother how to cook them; and the Irishman had a fine repast.—The family tasted but did not like them very well. When it was time to harvest them, he dug them, and grandmother had baked some large hard shelled pumpkins. They took one of the largest, and put up their whole winter's store of this now very valuable article. The shell contained a plenty for their winter's use, and to plant in the spring, and some to spare to their neighbors. Grandfather liked Patrick so well that he hired him a second time; he planted the potatoes a second time, when they raised so many they did not know how to dispose of them. My grandmother had not the convenience of the old lady at Lynn, they did not raise any gourds. Yours, respectfully,

JAMES WALKER.

(From the New England Farmer.)

CULTURE OF LUCERNE.

Columella estimated this plant as the choicest of all fodder because it lasted many years, and bore being cut down four, five or six times a year. It enriches, he says, the land on which it grows, fattens the cattle fed with it, and is often a remedy for sick cattle. Columella's observations were adapted to the climate of Italy, and lucerne is not so productive in colder countries. London says, though lucerne was so much esteemed by the ancients, and has been long cultivated to advantage in France and Switzerland, it has yet found no great reception in England. If any good reason can be given for this it is, that lucerne is a less hardy plant than red clover, requires three or four years before it comes to its full growth, and is for these and other reasons ill adapted to enter into general rotations.

The soil for lucerne must be dry, and inclining to sand with a subsoil not inferior to the surface; unless the subsoil be good and deep it is not fit for lucerne. The ploughing should be deep and thorough, and English writers advise to bury a coat of manure a foot below the surface. Such is the practice in Guernsey, where lucerne is highly estimated.

Capt. J. Swett, of Roxbury, has cultivated this grass to good advantage. In September, 1831, this gentleman sent a sample to the Mass. Hor. Soc. and observed, "This grass is of the fourth crop this season, and according to my estimate has produced at the rate of about 3000 lbs. per acre each crop when cut and dried. I have raised this grass the last three years and find that my horses and cows like it much. I prepare my land in the following manner: have it ploughed twice, harrowed well, and all the weeds and rubbish taken from the land, then sow about 30 lbs. of seeds to the acre."

The quantity of seed made use of in Europe is from 15 to 20 lbs. to an acre, though Mr. Swett thinks more would be better. The Hon. Robt. R. Livingstone has cultivated lucerne with much success. He advises, as the result of his experiments, 1. Never to sow on ground which is not perfectly pulverized. 2. Not to sow till the ground has acquired a degree of warmth friendly to vegetation, viz. in May. 3. To sow with no crop that will probably lodge. 4. If sown with buckwheat to apply no gypsum or other manure till the wheat is off. 5. If the quantity sown is small and the farmer can afford to lose a crop, to give the

ground one turn in autumn, another in April, harrowing fine, and a third the beginning of May, and then if the weather be mild and warm sow, if the ground be in perfect tilth; otherwise give it another ploughing.

When lucerne turns yellow it should be mowed, and the plants will come up free from disease.

(From the Southern Agriculturist.)

OBSERVATIONS ON THE CULTURE OF GRASSES.

MR. EDITOR:

No one knows better than myself, the impatience with which the planters of Georgia and South Carolina listen to recommendations to cultivate grasses. A large majority of them, by excessively overtasking their hands and horses in crops of corn and cotton, are obliged to run every thing almost off its legs, during the summer months, to keep down the crab and crow-foot grasses; these little spontaneous productions of the earth are regarded as the worst enemies to agricultural thrift, and one advising the use of any means to promote their growth, little better than a simpleton. Yet, with the exception of three or four of the southern states, there is no other country on the face of the earth, (so far as my information extends,) where grasses are not cultivated as an article of prime value to the husbandman. In most parts of Europe and the states of our Confederacy north and west of the Carolinas, lands which have any peculiar adaptation to the production of grass, bear a current price of double or treble that of arable, high and dry lands.

The planters of Georgia and Carolina are not more remarkable for these opinions and practices, in respect to the use of grasses, than are the fields they plough, for the wasted and hopeless condition of the soil, and the starved and shabby cattle that approach them in the intervals of crop growing. Have not these matters the relation to each other, of cause and effect? I cannot doubt it. Is there a probability, in any climate or country, of preserving the fertility of fields without an habitual and extensive use of the grasses? No instance is recollected; and the total disuse of this branch of husbandry sufficiently accounts for the conversion of parts of Maryland, of Virginia, the Carolinas and Georgia, from a state of great original fertility, to one of barrenness.

I know it has been said a thousand times, that our climate is too arid for grass, "that this is a bad grass country, &c.;" but we also know that in the South of Europe, in North Africa, and in parts of Asia, corresponding in latitude and with a higher mean temperature than ours, that grasses are objects of systematic care with husbandmen, and their fields are not, in the cant phrase of our country, "worn out." So far, indeed, are they from being worn out, that in many provinces of Italy, Spain and France, under the discouragement of the vilest governments that ever cursed the life of man, they have become more fertile.

It is often said, too, among southern planters, that grass must not be cultivated for hay, because the corn blades supply an abundance of better forage. If our dwarfish "skin and bone" cattle and horses, had a vote on that question, it would be decided otherwise.

Beside the incalculable advantages of having on hand at all times, a bountiful supply of good hay forage, and the consequent production of much manure, the roots and tops of the various grasses and other plants with which this country does or might abound, it is believed would sustain the fertility of our fields under a moderate course of cropping. The mass of vegetable matter that is found in the crab-grass roots, the growth of one season on an acre of land, would surprise most persons who have never seen them collected in heaps. Having once had occasion to plough and rake up the grass roots from a small plat of tolerably rich land, I found the quantity scarcely less than ten fold what had been expected. It was this

accidental development that explained, what had previously been a matter of some wonder; that our fields without any care of the soil, and under an unceasing course of exhausting crops for nearly forty years, should be found capable of producing any thing. I saw at once, that it was the roots of the crab-grass, this dire enemy of cotton and corn, this pest of the planter's life, which had enabled him, in spite of all his foolish improvidence, to keep himself and family alive.

I am apprized of no experiments in this state that would encourage a planter to import and cultivate foreign grasses; at any rate, before he had made a fair trial of those that are indigenous, and which are known to grow on moderately fertile fields by the use of one ploughing, followed by the harrow. Red clover, sainfoin, lucerne and orchard grass, have been sown, and managed indeed, very badly, without much good result, except in resting the fields where they had a brief existence of a year or two. Among the foreign grasses which I have tried on high and dry land, the orchard grass has succeeded far the best. It grows on worn land, stands our hardest winters so well as to furnish better pasturage for calves and milch cows than rye oats, and the roots are so abundant as to add a great deal of vegetable matter to the soil in which it is permitted to grow as long as three years. On account of its abundant roots, its flourishing in cold weather, and keeping possession of the ground for several years, it is preferable to crab-grass; though less valuable as a fertilizer than red clover with its long tap root. HIGHLANDER.

Lime, combined with phosphoric acid is the basis of the bones, and is found also in the fluids. Shells consist of carbonate of lime; and hence their remains have been considered as the basis of limestone mountains. Silica and manganese are found in the hair. Iron with phosphoric acid, constitutes part of the blood.

HORTICULTURE.

(From the New England Farmer.)

THE SPANISH CHESTNUT, (*Castanea vesca*.)

The Spanish chestnut is one of the most magnificent of the European trees, exceeding the oak in height, and equalling it in bulk and extent. It has long been naturalized to the southern countries of Europe. It is said that Tiberius Caesar first brought it from Sardis in Lydia to Italy, whence it was introduced into France, Spain, and Britain. It is indigenous, also, in many parts of Asia, in China, Cochinchina, Japan, &c. It grows in the greatest abundance, at present, in the mountainous parts of Italy, in the south of France and Spain, in Switzerland, and many parts of the Alps towards Italy, in Corsica and Sicily, where it grows half way up Mount Etna.

This tree seems to be very long lived, and grows to a very great size. The famous *Castagno de Cenio Cavallo*, on Mount Etna, as measured by M. Brydone, in 1770, is 204 feet in circumference; some, however, have doubted whether this is really one tree. Brydone says, it had the appearance of five distinct trees, but that he was assured the space was once filled with solid timber, and that there was no bark on the inside. Kircher, about a century before Brydone, affirms that an entire flock of sheep might be commodiously enclosed within it, as a fold. *Il Castagno del Galea*, of which there is no doubt, measured then seventy-six feet round, at two feet from the earth. But those trees grow on a deep, fertile soil, formed from the ashes of the volcano.

This tree deserves our care as much as any which are propagated in this country, either for use or beauty; being one of the best sorts of timber, and affording a goodly shade. The leaves continue late in the autumn, turning then to a golden hue; nor are they so

liable to the depredations of insects. The fruit is a desirable nut for autumn or winter, and is eaten roasted, with salt, and sometimes raw. It is the usual, and in some places almost the only food of the common people in the Apennines of Italy, in Savoy, and some parts of France and Spain. They are not only boiled and roasted, but puddings, cakes and bread are made of them. "Chestnuts, stewed with cream," according to Phillips, "make a much admired dish, and many families prefer them to all other stuffings for turkeys. It is considered to be a flatulent diet, and hard of digestion; yet there are instances in Italy where men have lived to the age of 100 years, who have fed wholly on chestnuts. These nuts are used for bleaching linen, and for making starch; they are also reputed excellent food for deer, sheep, and other domestic animals. The wood is used by the cabinet maker and cooper; makes an excellent cup-cupice tree, for poles and hoops; the bark is equal in astringency to that of the larch and mountain-ash for tanning; the wood is also esteemed for timber and fuel.

Propagation and Culture.—This tree is propagated by planting the nuts early in spring in beds of unmanured sandy loam with a dry bottom, but will grow in any soil, on a dry sub-soil. Before planting, it will be proper to put the nuts into water to try their goodness, which is known by their weight; those which swim are generally good for nothing; but such as sink to the bottom are sure to be good. In planting, a drill should be made about four inches deep, in which the nuts should be placed at about four or six inches apart, with the eye uppermost; then draw the earth over them with a rake, or some other suitable instrument; then make a second drill at about the distance of a foot from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet wide, for the convenience of cleansing the beds, &c. In about three months the nuts will appear above ground, after which, they should be kept clear of weeds, especially when young. In these beds they may remain for two years, when they may be removed into a nursery at a wider distance. The best season for transplanting is late in autumn, or early in spring. The time generally allowed them in this nursery is three or four years, according to their growth; but the younger they are transplanted, if designed for timber, the better they will succeed. They should be kept clear of weeds, observing to prune off lateral branches, which would retard their upright growth; and when they are disposed to grow crooked, they may be cut down to the lowermost eye, next to the surface of the ground, the first year after planting, which will cause them to make one strong upright shoot, and afterwards may be trained into straight, good trees. After having remained three or four years in this nursery, they may be transplanted, either in rows to grow for timber, or in quarters to grow for wilderness plantations, avenues, clumps, or the orchard. If they are intended for timber, it is much better to transplant them and let them remain unmoved; for these trees are apt to have a downright tap-root, which, being bent by transplanting, is often a check to their upright growth. But when they are intended for fruit, permit the trees to branch out freely above, mostly in their natural order, to advance in large regular heads. Give occasional pruning only to very irregular and cross branches, and low stragglers. After they have attained some tolerably branchy growth, they will come into bearing in moderate plenty; and when they have expanded into large, full heads, they may be expected to yield in abundance.*

The foregoing remarks will, I hope, have some tendency to encourage the growth of this invaluable tree in this country. There can be no doubt of its succeeding to perfection in the middle and western

* See Loudon's Encyclopedia of Gardening, and Miller's Gardeners and Botanists' Dictionary, by Martin.

states; and a high probability in the northern. Every patriot and friend to posterity can do no less than make the experiment. Let us hope, however, to see it rear its head among our forests and plantations, and, ere many years, be a source of health, ornament, and of profit. B.

NOTE. A quantity of the nuts have recently been imported by I. Thorndike, Esq., of Boston, for gratuitous distribution to those who wish to make the experiment of cultivating them. Small parcels may be had gratis at the office of the New England Farmer.

(From the Genesee Farmer.)

GRAFTING.

*Volusia, Chatahque county,)
March 1, 1853.)*

MESSRS. EDITORS:

Will some person, through the columns of the Genesee Farmer, answer the following questions? Is it possible to make a red and green apple scion grow together so as to produce fruit, one-half of which shall be red, the other half green? that one-half may be sweet, the other half sour? If so, how is it performed? Is it by grafting, or by inoculation? What season should grafts be set? and what time in the summer should inoculation be performed?

REMARKS BY A CORRESPONDENT.—In reply to the above, we answer, that there is no doubt but that two scions may be split longitudinally, and nicely fitted together, and thus be ingrafted to a common stock; but whether the fruit would partake of both parents, is quite apocryphal. It seems to us, as the scion grew and lengthened itself, it would still preserve its identity, as undoubtedly would each bud which should sprout from the original scion; if a blossom bud should start from the wood at the very line of union, we are not prepared to say what would be the result. We have never seen an apple of the two colors so distinctly marked as to indicate an operation of this kind, but there are many instances of apples half sweet and half sour; and we were last fall shown a limb with the apples attached, alternately sweet and sour, which was characteristic of the whole tree. It has been often asserted, that the half sour and half sweet apples were produced by the splitting of the graft, or the bud, in inoculation; while others have asserted that it was a premature ripening of one side of the fruit.

The peach and the plum will graft and bud together; what would be the consequences if this union should take place? ripening at different periods, a rough skin and a smooth one, stones of a different size and form—it would certainly be an anomaly in nature.

The best season for budding is at any time after the formation of the new bud, when the bark will peel freely on the stock. If put in too early, they are apt to start late in the season, and not ripen their wood.—July and August are the best months. Grafting is preferable to budding in all cases except on small and young stocks, or with the peach, nectarine and apricot.

(From the Northern Farmer.)

HIGH BUSH CRANBERRY.

MESSRS. NEWTONS: *Newport, May 1850.*

In the New England Farmer of the seventeenth of April last, a correspondent inquires of the readers of that paper whether any of them "know of the high bushed cranberry; where any of it grows, and if so, whether it can be obtained in any considerable quantity?" Not having seen any answer to that inquiry in the New England Farmer, I have thought proper to communicate through your valuable paper, some particulars in relation to that shrub, which is said by the correspondent of the New England Farmer to be "an extensively valuable medical plant—although its virtues are very little known."

The high bush cranberry is a beautiful shrub, grows from ten to fifteen feet high, and is exceedingly fruit-

ful; producing great numbers of large clusters of berries, resembling the low cranberry in appearance and taste, though I think of a pleasanter acid. The berries are not quite as large as those of the low species, and have a hard stone or seed in them of considerable size, like that of the cherry, though of different form, being thin and flat, instead of globular. This beautiful shrub is indigenous in New Hampshire; is common in the western part of the state, and is occasionally found in the gardens, and about the dwellings of our citizens. Its favorite location is on the interval lands near brooks and rivers, where it grows luxuriantly; but is, I believe, never found on low meadows, or wet and swampy lands. Z.

[The shrub above spoken of is the *Viburnum oxycoccos*, and belongs to an order very different from the cranberry. It is a tolerable ornament in a shrubbery, but of very little, if any use in the kitchen.—*Ed. Amer. Farmer.*]

RURAL ECONOMY.

(From the New England Farmer.)

ANALYSIS OF DIFFERENT SORTS OF SALT, &c.

Jamaica Plain,)
April 29, 1833. }

T. G. FESSENDEN, ESQ.

Sir,—In your N. E. Farmer of 7th March, 1832, you published an article furnished by me, on the subject of salt, (in consequence of an article from the N. York Medical Repository by Dr. Mitchell on the *destructive qualities of Liverpool Salt*), in which paper I gave you an extract from Ure's Chemistry, 4th edition, 1822, an analysis of eleven sorts of salt. And my expectations of being enabled to furnish you an analysis, by an able chemist of our own country, of several foreign as well as American salts.

I procured eight samples, as per particulars below, and President Quincy was so obliging as to request Dr. Webster, Professor of Chemistry of Harvard University to analyse them. He has sent me the result which I now give you of 500 grains of each.

	Muriate of Soda.	Sulphate of Magnesia.	Sulphate of Lime.	Aluminous matter.	Muriate of Magnesia.	Muriate of Lime.	Insoluble earthy matter.
1. Sicily coarse salt,	478	4½	2½	4½	2½	1½	6½
3. Eastport, Me.	491		3½		2½	1	2
4. New York, fine,	183	5½	5½		4	2	
7. St. Ubes, coarse,	179½	2	10		2	1½	4½
9. Quincy, Mass.	484½	3	5			4½	2
8. Native rock or mineral salt from Cheshire, Eng. }	491½		3½				5

No. 2. Liverpool coarse fine. The Muriate of Soda and other constituents agreed so nearly with the results from No. 8, as did the results from No. 6, (Liverpool finest,) that I find them noted on my book as the same, differing only in the state of mechanical division.

No. 5. Turks Island salt, very nearly the same results as No. 1. In the sample from Sicily, No. 1, I obtained indication of a minute proportion of iodine.

I. W. W.

No. 3 was a specimen of salt manufactured at Eastport, in Maine, (from the English Cheshire Rock or Mineral salt.) Large quantities of it are there manufactured, and it appears to possess precisely the qualities of Liverpool salt *all of which* I believe is manufactured from the Mineral rock and springs of Cheshire.

No 4 was from a basket of fine table salt manufactured at one of the salt establishments in the western part of New York.

No 9 was a specimen of salt from President Quincy's own salt works at Quincy, Mass., evaporat-

ed from sea water. His works have long been considered as producing it of superior quality.

After the examination, of the different salts usually for sale in our markets, I trust there need be no longer any fear in using them, on account of any bad properties they may have been supposed to possess. Only bearing in mind that their use should be by *weight*, not *measure*. If for butter I have no doubt the fine Liverpool or Eastport is as good as any other, provided the butter be well made and thoroughly worked.

I have for many years had no other used, till the past year I purchased the best Turks Island I could find, and had it well washed and ground fine. We do not perceive the least difference in the butter, having used precisely the *same weight*.

There is no doubt for packing *meat and fish* the *coarsest* salt should be used, as keeping the meat separate, and being longer in dissolving.

Yours, truly,

JOHN PRINCE.

(From the New England Farmer.)

SOWS AND THEIR PIGS.—ANIMAL FOOD FOR SWINE, &c.

MR. FESSENDEN: New Bedford, May 1, 1833.

In your paper of April 3, I observed an article by "A Subscriber," the writer of which recommends animal food to be given to sows just before farrowing, believing it will prevent them from destroying their pigs. He recommends fresh meat; I will go further and say, that my experience tells me that salt meat, either raw or boiled, will produce the same beneficial effect.

I have since seen another article in your paper over the signature of "Berkshire," the writer of which does not agree with your "Subscriber," does not "come to the same conclusions," but takes other ground—recommends another mode of treatment, a mode that is *not indispensably necessary*, as I shall prove by and by.

He says, "The nature of swine is to feed on almost any thing that comes in its way, but its natural food is vegetable rather than animal," &c. It may be so, but who is there that does not know that swine are extremely eager after animal food at *all* times, that they will *always* leave vegetable for animal food—and who can say, but that at or near the time of farrowing some of them may have still stronger inclinations for animal food? Perhaps some sows would not destroy their pigs under any circumstances as to food or location, while others from some cause unknown to us, are induced to commit an unnatural act.—"Berkshire" says, "In cases where the pigs come late in the season and the sows have had the opportunity of coming to the ground and working in it, and collecting grass, roots, &c. I have never known any of the difficulties complained of by your correspondents."—He then recommends, that when from necessity sows are kept in a close pen and from the ground, giving them a *suitable supply of potatoes, turnips, ruta бага, &c.* which he thinks will remove the difficulty complained of.

I will now inform Mr. "Berkshire" of a little of my experience, and leave him to make his own comments—I have seen more than twenty broods of as fine pigs as ever were seen in a farm yard, farrowed in a house the dimensions of which did not exceed eight feet by three and a half or four, and raised on the deck of a *whale ship at sea*, where there was no earth for the sows to work upon—no grass—no roots to be collected, and what was still worse, there were no *potatoes*—no *turnips*, nor *ruta бага*, not even for human, much less to furnish a "suitable supply" to feed swine upon.—Yes, I have raised pigs that have lived to farrow pigs, that never sat a hoof on terra firma, that never had the pleasure of sticking their noses in the earth for the purpose of *collecting grass, roots, &c.* and I do not recollect of ever having a pig destroyed.—I don't wish to be understood that I *always* give my sows animal food—it was not the case; but I have frequently done, and believe in its salutary effects.

Now, Mr. Fessenden, if you are not surfeited with the subject, but intend "going the whole hog," please insert in your next paper, for the information of Berkshire and others concerned, the opinion—the experience—and the plain unvarnished tale of a New Bedford

WHALER.

(From the Cabinet Cyclopædia.)

HINTS TO HOUSEWIVES.

Vessels intended to contain liquid of a higher temperature than the surrounding medium, and to keep that liquid as long as possible at the highest temperature, should be constructed of materials which are the worst radiators of heat. Thus, tea-urns and tea-pots are best adapted for their purpose when constructed of polished metal, and worst when constructed of black porcelain. A black porcelain tea-pot is the worst conceivable material for that vessel, for both its material and color are good radiators of heat, and the liquid contained in it cools with the greatest possible rapidity. On the other hand, a bright metal tea-pot is best adapted for the purpose, because it is the worst radiator of heat, and therefore cools as slowly as possible. A polished silver or brass tea urn is better adapted to retain the heat of the water than one of a dull brown color, such as is most commonly used. A tin kettle retains the heat of water boiled in it more effectually, if it be kept clean and polished, than if it be allowed to collect the smoke and soot, to which it is exposed from the action of the fire. When coated with this, its surface becomes rough and black, and is a powerful radiator of heat. A set of polished fire-irons may remain for a long time in front of a hot fire, without receiving from it any increase of temperature beyond that of the chamber, because the heat radiated by the fire is all reflected by the polished surface of the irons, and none of it is absorbed; but if a set of rough, unpolished irons, were similarly placed, they would become speedily so hot, that they could not be used without inconvenience. The polish of fire-irons is, therefore, not merely a matter of ornament, but of use and convenience. The rough, unpolished poker, sometimes used in a kitchen, becomes speedily so hot that it cannot be held without pain.—A close stove, intended to warm an apartment, should not have a polished surface, for in that case it is one of the worst radiators of heat, and nothing could be contrived less fit for the purpose to which it is applied. On the other hand, a rough, unpolished surface of cast iron, is favorable to radiation, and a fire in such a stove will always produce a most powerful effect.

CHURNING ON HORSEBACK.

We have just been told, by a gentleman who has travelled in South America, that the Indians near Buenos Ayres *churn their milk on horseback*. They have plenty of horses, and they are taught very early to ride with skill; so that when they wish to churn they put their milk in a tin canister or any other convenient vessel, and taking it on horseback, gallop off several miles, till by the sound it makes in the churn, they know that the butter has separated from the buttermilk. Even little boys perform this service, for so well do they train their horses, that if the rider wishes to have his beast turn towards the right, he holds out his left hand, and presses the bridle rein gently against his neck; and if to the left, he holds out his right hand, and presses the right rein; the horse always turning in an opposite direction, as if to get away from his hand.

Our informant says, that on seeing a little Indian boy come galloping along one day with his churn, he asked him to stop, and inquired how far he had rode. He said about two leagues, (six miles.) On being asked how much farther he should go; he said about one more league. On opening the churn, the butter was already beginning to separate. Probably another league was sufficient to complete the process.

TWO IMPORTED MALTESE JACKS FOR SALE.

These animals were purchased in Malta in June, 1892, by two officers of the U. S. ship Concord, in which they were imported. The selection was left to one of the best judges in the island, who advertised three months previous to purchasing, for the largest and best bred Jacks, without regard to cost—more than one hundred were offered before a choice was made. They are now about three years old, and stand, one 13½ and the other 13½ hands high, and will yet grow three or four inches; their color is black with fawn nose, eyes and belly. In size, action and vigor, they were believed to be unsurpassed by any Jacks in Malta, and they have been pronounced by good judges, the finest ever brought into the United States. It is deemed unnecessary to say any thing about the superiority of the Malta Jacks; it being well known that they are of the high bred stock of Persia and Arabia.

These animals may be viewed and every information respecting them, may be obtained, by applying to I. I. Hitchcock, American Farmer establishment, Baltimore. The price is \$600 each.

PUBLIC SALE OF DURHAM SHORTHORN-ED CATTLE AND HIGHLY IMPROVED SHEEP.

Will be sold on Wednesday, 29th day of May next, on the *Lucky Hit Farm*, Frederick county, Virginia, the late residence of Richard K. Meade, dec'd, the highly improved stock of CATTLE and SHEEP, belonging to the estate of said dec'd. It is believed that the stock now offered for sale, stand unsurpassed, in the valuable qualities of their kind, by any in our country. Amongst the Durham Cattle are several BULLS, from a few months up to three years old, handsomely marked and of fine figure and size; there are also a number of young COWS, some of them with calves by their sides; and a handsome collection of HEDGERS less than a year old, and well grown.

The SHEEP are equally remarkable for the quantity and quality of their wool, and for their uncommon thriftiness. They are the result of the unremitting care and attention to the subject, by the deceased, for the last twenty-five years. The flock consists of about one hundred and fifty, males and females, and nearly an equal portion of each. The Ewes have at this time young Lambs by the most approved Rams on the place. They will be sold in small divisions, with a view to the general accommodation.

A credit of nine months will be given, the purchaser giving bond and approved security, but a discount will be allowed to any that may prefer paying the money in hand.

DAVID MEADE, Administrator.

April 5,—St

WHITE MULBERRY SEED, &c.

Just received at the American Farmer Office and Seed Store a supply of fresh and genuine White MULBERRY SEED. Also

MAMMOTH PUMPKIN SEED.

EARLIEST FRENCH CABBAGE do.

EARLY FRENCH, or PARIS WHITE ONION do.

ACORN SQUASH do.

Together with a complete assortment of Fresh Garden Seeds, including those raised by the United Society of Shakers at New Lebanon, N. Y.

I. I. HITCHCOCK.

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at 75 cents per bushel.

I. I. HITCHCOCK,

American Farmer Office and Seed Store.

TO WINE DRESSERS.

The Subscriber wishing, to engage a Wine Dresser to take charge of a flourishing and fruitful Vineyard, offers the most favorable terms to a person who can furnish testimonials of a good character.

For particulars apply to I. I. HITCHCOCK, American Farmer Establishment, or to the undersigned by letter, addressed to Brown's Mills, Mifflin Co. Penn.

May 24. t f.

JOSEPH HENDERSON.

HERBEMONT ON THE VINE AND WINE MAKING

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States." By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Scythes, Grain Cradles, Scythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

HARVEST TOOLS, WHEAT FANS, &c.

SINCLAIR & MOORE, have in store, and are manufacturing a general assortment of HARVEST TOOLS, among which are

100 WHEAT FANS, double and single geared.

300 Grain CRADLES, with Scythes complete. This article is made of the best and most durable materials, and will be warranted as such.

50 doz. Grass and Grain SNEATHS.

30 do. Hay and Manure FORKS.

30 do. RAKES and Wooden tined FORKS.

SCYTHES and Sneaths, hung ready for use.

SICKLES, English and American Scythe Stones, Strickles, &c. &c.

Their Stock of CASTINGS, Agricultural Implements, Garden Tools and SEEDS, is as usual full and complete.

Also, just received from Europe, two bales, containing Lucerne and Ray Grass, Cabbage, Radish, Lettuce, and many other valuable SEEDS of last year's growth. From the appearance of this lot of Seed; and the respectability of the establishment from which they were imported, they can with the greatest confidence recommend them.

May 24.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—An advance will be noticed in flour. The wagon price of Howard street remains at \$5.25; some few purchases have been made, however, at \$5.31, and one or two at \$5.37½. Wheat fluctuates, and varies considerably, according to quantity in market, and quality of parcels; showing that a tolerable supply would soon reduce the price.

Tobacco.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 1.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 8.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 659 bbls. Md.; and 124 bbls. Ohio—total 783 bbls.

CONTENTS OF THIS NUMBER.

Editorial: Wine Dresser wanted; Farmers and Office; Splendid Flower, *Crimum amabile*; State of the Weather and Gardening in England—Culture of Tobacco in Prince George's County, Md.; Inquiry—Remedy against Bee-moth—Roses in Sinclair and Moore's Nursery—Foreign Markets—Letter from A Virginian on Horizontal Ploughing and Hill-side Ploughs—Answers to Queries on the Culture of Rice—On the Culture of Rice on Highlands—New Potatoes—On the Cultivation of Indian Corn, by William Clark, Jr.—Ficht Culture of Peas—First Introduction of Potatoes, by James Walker—Culture of Lucerne—Observations on the Culture of Grasses in the Southern States—The Spanish Chestnut, *Castanea vesca*, Propagation and Culture—On Grafting—High Bush Cranberry—Analysis of Different Sorts of Salt, &c.—Sows and their Figs; Animal Food for Swine—Hints to Housewives—Churning on Horseback—Prices Current of Country Produce in the New York and Baltimore Markets—Advertisements.

Special Agents for the American Farmer.

The following persons are authorized to act as Agents for the American Farmer in the several places of residence:

Boston,	John B. Russell, N. E. Farmer Office.
New York,	J. H. Gourin, at the Post Office.
Philadelphia,	{ D. N. C. Landreth, 85 Chestnut street.
	{ B. E. Freymuth, Marble Court.
Washington, D. C.,	{ P. Thompson.
	{ Cole & Co.
Petersburg, Va.,	Thomas Coleman.
Raleigh, N. C.,	Joseph Gals & Son.
Charleston, S. C.,	P. Thornton, Post Master.
New Orleans,	Wm. McKim.
Mobile, Ala.,	Eichbaum & Norvell.
St. Louis, Mo.,	Frederick Stauden.
Port Gibson, Mis.,	Bassmore Hoopes.
Salem, N. J.,	H. H. Elwell.
General Agent for the State of Maryland, T. B. Brennan.	

➤ DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "I. I. Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, MAY 31, 1833.

"LADIES' HORTICULTURAL MAGAZINE AND FLOREL R. GISTER."—The prospectus of a monthly journal, with the above title, to be published in Baltimore, by H. F. Dickehut, Esq. has been put into our hands. The first number is to appear in September next, if a sufficient number of subscribers is obtained, and the price is five dollars per annum, payable on delivery of the first number. The work is intended to embrace all subjects connected with *ornamental horticulture*, and is therefore appropriately dedicated to the ladies, for whose use and amusement Mr. Dickehut is certainly well qualified to render it valuable.

FRUIT TREES, CATERPILLARS, &c.—A very intelligent young friend of ours, who had seen a remark in a late Farmer, on the existence of caterpillars to an unusual extent this season, informs us that his orchards have escaped the ravages of these insects this season entirely; and he believes the cause of this exemption to be fairly attributed to his practice of scraping the bodies of his trees in the winter. He says he scrapes all the dry scaly bark off, with the scraper used in scraping vessels, at any time after the commencement of winter, and before the rising of the sap in spring. He thinks that these and other insects deposit their eggs beneath the dry scales of the bark, and that the larvæ emerge thence in the spring; but by thoroughly scraping the bodies of the trees he effectually destroys them. At all events his orchards are perfectly free from these and all other insects, while his neighbors' are infested by them as usual, and he resorts to no other means of protection. He says that one of his young orchards had produced very inferior knotty fruit, and it had been concluded that, though the trees were selected from one of the most respectable nurseries in the country, the varieties were bad. However, he determined to scrape the trees, as above, and the fruit the next season was fair, and of the quality originally expected from them.—These facts are from a source so respectable that we do not hesitate to lay them before our readers in the fullest confidence in the correctness of the inferences drawn from them. We have often seen the eggs and larvæ of insects concealed beneath the dry scales of bark on fruit trees; and it seems nothing but the simplest operation of common sense to infer, that the removal of them in winter would save the trees from the ravages of at least those insects that would have emerged from these cells at the commencement of warm weather. Every body knows that the destruction of one insect in spring, is equal to the extermination of some thousands in midsummer; and, therefore, we conclude, that an orchard may be protected from the caterpillar by the means practised by our informant.

THE GREAT GRAPEVINE.—Our friend Willis, of Oxford, Eastern Shore of Maryland, has furnished us with the following certificate of the number of bunches of grapes now on his great grapevine. It will be recollected that we have several times published the number borne by this vine heretofore: in 1831 we believe it was twenty-five thousand bunches, or upwards. The number this year exceeds any thing we ever before heard of, and we doubt whether a parallel can be found for it. Mr. Willis will please give us a history of this vine, with the name of the kind of grape.

Oxford, May 6, 1833.

We hereby certify, that we have counted the bunches of grapes, this day, that are on John Willis' grapevine, in his yard, of seven years' growth, as accurately as we could, and have made allowance for good count.—We find on it fifty-four thousand four hundred

and ninety bunches, besides many more young bunches appear to be coming out, and we are fully of opinion we have, by the rule we went by, allowed at least three thousand for good count, that are already in sight. No young growth that had not more than two bunches on it was counted; and we think at least one third or more are double bunches, and are only counted as single.

RICHARD MARKLAND.

AFRICAN BEANS—GAME BIRD.

Extract of a letter from Com. Porter to J. S. Skinner, Esq. dated

Pera, Constantinople, March 5, 1833.

I shall send you a few beans from Africa. They were given to me by His Excellency the Baron d'Ottenfels, the Austrian minister at this place. The following is what he says of them: "Haricots du Kordosan en Afrique," from the seed of 1832. To be sown in April or May, either in dry or wet ground indifferently, sheltered from the north wind. The thick stem furnishes an excellent charcoal for gunpowder. The beans are good for fowls and beasts, (bestiaux.) The plant cut up and mixed with manure gives to it great activity in enriching the earth.

We have a game bird here much resembling the swan in shape, and as large as a turkey. I will try and send you a drawing; in plumage they are like those fronting page 589 of the 3d volume of the Turf Register you sent me. I send you now one of the side leathers near the thigh, which may convey some idea of the size and beauty of the bird. It has but three toes, all standing forward, no hind claw or spur. They are called *Taroughau* by the Turks, which is the name for a turkey.

Yours, truly, DAVID PORTER.

SIREW SALT OVER YOUR ASPARAGUS BEDS.—The asparagus is a native of the shores of the ocean, and will bear so much salt without being injured, that most of the weeds that infest the beds may be destroyed in this manner. But the application has other advantages: salt is a valuable manure; and it also repels insects by its pungency; for though we know of none that feeds on the asparagus, there are many that would otherwise *pouch*, and lessen the fertility of the soil.—*Genesee Farmer*.

(From the Richmond Compiler.)

NEW OIL MILL.

We have called the attention of our readers several times to the very useful art discovered by Messrs. Smith & Follet of Petersburg, of hulling the cotton seed and extracting oil from the kernel. We observe by the "Natchez Journal," of the 3d inst. that it is about to be applied on a very large scale in the west, where cotton is raised, and the seed may be obtained in the greatest quantity. We had heard of this establishment being about to be made in the west, under a patent right purchased by Messrs. A. Plummer & Co. of Messrs. Smith & Follet. The Journal informs us, that the company have erected at Natchez a substantial building, eighty-four feet by eighty, and one and a half stories, which comprises a steam engine of twenty two and a half inch cylinder, and five feet stroke, driving eight hulling machines, five set of stones, and a machine to prepare and grind the kernel for heating—eight cylinders for heating the meal; a corn and seven lever presses in proportion.

It is the largest establishment for making of oil in the United States—and capable making from one to two thousand gallons per day. There are but two other cotton seed oil factories in the union—one in Petersburg, and the other in North Carolina, "scarcely more than a tenth as large" as that which Mr. Plummer has established in the city of Natchez.

It is ascertained that *one bushel of seed will make three quarts of oil*. It is said to be "among the best of paint oils—it is easily refined—it answers as well as the very best winter strained sperm oil for lamps, without the least disagreeable smell, answering admirably well for woollens, machinery, &c." Exclusive of the oil, the cake is the very best of food for cattle, &c. The planters have given every facility in their power for supplying seed chiefly to the mill—and have promised to save the seed of their present crop, and on the best terms, for the new establishment.

Mr. Plummer has made arrangements for making a similar establishment in Florence—and also one in Mobile, state of Alabama.

We cannot entertain a doubt, that this manufacture will be eminently profitable to the proprietor and useful to the public. We were favored during the last autumn with specimens of the oil from the Petersburg factory. The one was the first extract from the seed—of a yellowish hue, and very transparent. The other was the refined oil, which was as limpid and clear and light colored as water itself. It seemed admirably calculated for painting, lamps, &c.

THE HORTICULTURAL SOCIETY OF MARYLAND.

For the diffusion of Horticultural Science and the Improvement of the Art of Gardening; Associated Nov. 20th—Incorporated by act of the Legislature, at December session, 1832.

The Council of this Association have resolved to open the public proceedings of the Society, by an Exhibition of Plants, Flowers, Fruits and other Vegetable productions.

The Exhibition will be opened on the eleventh day of June next, and will continue during that and the following day.

On the eleventh of June, popular lectures will be given in the hall of exhibition, and on the twelfth the society will hold a public meeting, when an address will be delivered.

In furtherance of the views of the society, the Council have resolved to offer premiums to the aggregate amount of one hundred dollars, to be awarded to the finest objects exhibited, by a committee of Judges appointed for that purpose.

The following gentlemen have been appointed to act as committee of arrangement, viz: H. F. Dickehut, chairman, Z. W. Bates, Geo. Fitzhugh, James Moore, Edward Kirtz, I. I. Hitchcock, Sam. Feast, John Feast.

All who feel interested in the advancement of Horticulture, are invited to lend their aid in furtherance of this design. Those wishing to exhibit plants or other objects of Horticultural interest, will please communicate their views to the committee of arrangement, stating at the same time the articles they design to exhibit.

Letters on the subject, must be addressed to the chairman of the committee, from whom any further information may be obtained.

May 3.

FOREIGN MARKETS.

HAVRE, April 13, for the week.

Cotton—We have received 9751 bales: the sales are 5299 bales. The demand was calm the first day, but was more extensive at the close; 2161 bales Louisiana at 98f. a 122f. 50; 1174 Georgia, at 96f. 50 a 104f. Some ordinary lots sold at 90 a 95f. Such as a year ago obtained 70 a 75f. Stock 28,000 bales.

Rice remains in small demand; 60 tierces Carolina sold at 22f. 25 for fair, to 24f. a 24f. 25 for good.

April 16—Sales of Cotton.—Louisiana 82 bales, at 108f. 102f.; do. 23 do. 102f.; do. 51 do 97f.; do. 46 do. 76f. 50c. Upland, 102 bales, 102f.; do. 280 do. 100f.; do. 75 do 100f.; do. 523 do. 99f. 50c.; do. 76 do. 98f.; do. 75 do. 98f.; do. 100 do. 97f. 50c.; do. 112 do. 97f.; do. 60 do. 96f.

AGRICULTURE.

ON AGRICULTURAL SCHOOLS.

[The following article, by the late Richard K. Meade, Esq. of White Post, Va. will be read with increased interest, now that excellent man has passed from amongst us. He sent it to us a day or two before his death, and it was accidentally mislaid.]

[Ed. Am. Far.]

(From the Virginia Farmer.)

Lucky Hit Farm, near White Post, Frederick Co. Va. }
 Mr. THEODORICK M'ROBERT: Jan. 7, 1833. }

Dear Sir,—It gives me much pleasure to acknowledge the receipt of yours, of December, and the accompanying numbers of the Virginia Farmer. I have long been zealously of the opinion, that such a paper, well edited, will greatly improve the indifferent state of our agriculture, and in contributing to uphold and sustain a cause so generally interesting, it will of course, reward the devotion of any individual whose talents, taste and interest, will combine with ordinary selfish views a high sense of the obligations imposed on all those who have the honor of laboring in the agricultural cause, esteeming it in a liberal, enlightened and expanded sense, the cause of virtue and improving humanity, and not merely the cultivation of the earth, increase of its fertility, or multiplication of its productions. The price of a subscription is a judicious and happy one for the accommodation of almost all farmers who have not imbibed prejudices against learning from the experience of others, or who cannot read their mother tongue. I should not be surprised, now that the ice is broken, that we should have in Virginia, several in no great lapse of time, especially, in the way the American Farmer has suggested, in terms so noble and disinterested, that political papers should devote a portion of their columns to the cause. My judgment and affections have long dwelt with great anxiety on the importance of instructing our fellow citizens (who are chiefly farmers) in the better understanding of their own peculiar calling, connected with education, general and particular, and that sovereign and final remedy, to the restoration of our poor lands, and their ultimate perfection—the colonization of our free blacks in Africa—a subject which cannot, with propriety, be agitated in the South, without the most positive assurances that they who recommend its institution are as fully aware of the necessity of attending to every prudent and perfectly constitutional step leading to its consummation, as the bitterest enemy of the glorious scheme. I am only waiting for the aid, and connection of two gentlemen, whose taste and talents qualify them to progress in a work, to which I can add but little more, than great zeal and good wishes, with some imperfect plans and reflections, and a pleasant situation for an agricultural school. Should I be so fortunate in my lifetime to establish, on a good foundation, an institution bearing such a relation to Fellenburg's, as the political situation of our country will permit, and an agricultural paper, well edited, a reporter for it, embracing also colonization, it may prove to be a source of moral and political benefit to our country, and if so, will be a sweet reward for all my feeble attempts to promote the cause of agriculture. Your invitation to say something on the subject of agricultural schools, you see, I have accepted with pleasure, and have almost unavoidably become a great egotist. Too many of us cannot labor in this cause, which you appear so much devoted to; and I am sure I shall not withhold a iota of my poor contribution to promote the success of your plans. Your situation is a most favorable one, with friends intelligent and numerous I trust. Visit the legislature, and make what impression you can. You may find some zealous friends to the cause, when they return home. Press your arguments on the agricultural committee—send an agent to the counties around to procure subscriptions, and leave no stone unturned, to make your paper as valu-

ble as possible, at the cheapest rate. I send you a few pages, which may be considered a very insignificant part of the all important subject; however, it may have the effect of stimulating others to pursue it with zeal and talents.

I am, very respectfully, your sincere well wisher, and obedient servant,
 RICHARD K. MEADE.

It may be thought presumptuous in any individual however respectful his approach to the legislature of Virginia, to solicit the attention of an appropriate committee, to one of the most important subjects coming under their examination. But its magnitude and future bearing on the prosperous and happy condition of this commonwealth, is readily sought for as an apology for this hasty and very imperfect notice of the subject, believing it to be of more importance to bestow some consideration on the work immediately, than to defer it for a more perfect exposition; when, perhaps, some gifted individual will bring it before the legislature in such detail and perspicuity, as to enable our representatives to act upon it with the greatest advantage to the state. The present very hasty, contracted and imperfect notice of it, has been in consequence of a recent correspondence with the editor of the Virginia Farmer, a work we should sustain for the honor of Virginia, being the first attempt at an agricultural paper in the state; and a much more recent resolve to ask the favor of the agricultural committee to investigate it, if possible, as an obligation due to our common country.

A traveller, of education and observation, seeks to apply the Fellenburg mode of education to the interests of the United States, and in so doing, discovers an acquaintance, not only with ancient and modern history, but with the actual existence of the prominent institutions of the old world, and by a still more recent examination of those of the new. The splendid plans of Napoleon, for the encouragement of science in France is taken into view. Thence, passing over to North and South America, takes the most effectual means of becoming acquainted with the real political situation of the people by travelling amongst them, and estimating their character by their progress in science, learning and virtue, through the various institutions fostered to promote the rational liberty and happiness of man.

"Europe," he says, "is rich in learned men, poor in citizens, who can say they have become patriots by their public education. In America, the old Spanish colonies have but changed the name. Liberal institutions exist—liberty not; for the people have not been prepared for freedom by any education whatever. In the United States, the congress and the government mingle not with ecclesiastical affairs, but they occupy themselves, also, not with the education, and only with the instruction of the citizens; and in this concern, the United States have done more than any other nation. This public instruction is the most brilliant part of their administrations, and their political institutions, and yet how much remains to wish for. Education is the most essential of all political powers. Patriotic citizens ought to co operate with all their power to extend this foundation of national welfare, and if I do not judge erroneously, the good will exist so to do. Is it not possible to establish in the United States, Fellenburg's system, as that of a national education? I am disposed to believe it is.—And permit me, with reluctance, to say, that it must be very generally regretted, that amiable, and highly talented gentlemen, should now lift their voices and wield their pens against a cause they once nobly advocated, denouncing themselves for having plead in behalf of suffering humanity—congratulating others that they have returned to their right reason in the advocacy of perpetual slavery—praying never again to be permitted to return to such weakness of intellect and resolve as might endanger the prosperity and happiness of the United States, and of Africa in the colonization of free blacks."

Would that a thousand responses were made. I too, am disposed to believe it. Such faith would soon have the effect of exhibiting scenes of improvement altogether visionary to those who cannot conceive the advantages to be imparted to agriculture, through a peculiar and appropriate education. If merely the improvement of the soil, and the consequent increase of the productions of the earth, with the immediate pleasures and comforts always attending them, find a limit to our expectations, we should have but a partial claim to the countenance and support of the good and the wise. But, when it can be demonstrated that the dearest interests of society are involved in this peculiar system of education—that religion, morality, political soundness; through the medium of republican simplicity; economy, and our general prosperity, are to be sustained by it, we earnestly solicit the aid of the intelligent and the virtuous: the offering in short, of all who can possibly look forward through the kind Providence of the Creator of heaven and earth, who is making the weak things of the world to confound the strong," who is pulling down high places, principalities and powers, and establishing in their stead the rights of the human race. Education is the grand medium by which the magnificent work is to be accomplished. He who once spake light into existence in a moment, we have reason to believe, has ordained that moral light should be gradually spread throughout the world; and if in the course of its operation, many reverses, and apparent difficulties should occur, its friends must not relax in their faith or zealous works. In its accomplishment some of the best blood of the old, much of the treasure of the new world, will be offered as a willing sacrifice to the principles which are leading to the true liberty and happiness of mankind. It should be a grateful theme of contemplation to the people of this new world, (United States,) who are progressing in the arts of peace and civilized society, that if ever an occasion of bloodshed should occur amongst them, it will be in violation of those principles which have already been made sacred by the sacrifices of their forefathers, and not to acquire a single right or privilege essential to their happiness in the engagement of life, liberty, and our holy religion.

"Agriculture," this observer continues, "is the only foundation of public wealth, and consequently, a national education must proceed from that point—call it state if you please. Nature herself has directed the inhabitants of this country to adopt it. But agriculture in the United States is entirely different from that of Europe. Whoever would introduce the latter into this country, would make a ruinous calculation; and whoever would establish an institution similar to that of Hofwyl, cannot succeed, if he begins not to take the plough in the hand, and to study practically the American agriculture. I have often heard the objection, that this agriculture is at present in its infancy, particularly in the west, and I am aware of that. But in order to improve it, it will be necessary to know all the advantages, and the disadvantages of what ought to be improved. After an exact knowledge of the existing deficiency, it will be impossible to attempt improvements, and to bring the American agriculture where the European dwells, to the highest perfection." He goes on to sustain the importance of giving an agricultural education to the poorer classes.

"The children are retained in a simple career, in which they can live comfortably, satisfied with themselves and their employments—a tendency whose high importance cannot be doubted in political concerns. Odious feelings and jealous dispositions are destroyed in the bud. In this course of instruction no useful knowledge is refused, but every useless information rigidly removed. Mr. Fellenburg thinks that there is enough to do in concentrating their education, in the formation of their hearts and character, in upholding the faculties of their understandings, and the abilities of their hands. Every instructed proprietor who has studied and understood the aim and means of this plan, can found on his own property, a school for

the poor, and exercise over it all necessary attention to insure its success, provided he possesses force of character and energy of mind. In the Wehrly school at Hofwyl, there is no exclusive method to give a special account of; and nevertheless, there is in that school, an excellent kind of proceeding, that a good mind can understand, and every intelligent man learn. If he will take the trouble to reflect and study."—The accounts of this division of the establishment folly prove the fact, that these poor boys by their labor support themselves and the expenses of it, while in the course of twelve or fifteen* years, they are receiving an education the most appropriate and important to their own happiness, and the well being of society.

"In founding schools in the United States with the view of improving the poorer classes of society, all the principles of the Wehrly school, and the consequent proceedings should be adopted, but we should avoid the inconveniences inseparable from disadvantages, which result from circumstances appertaining only to Hofwyl. Allow me to make open and candid observations concerning the greater part of your country, whose political institutions I must forever admire. It is here, as in every part of Europe, impossible to observe closely the mass of the people without being struck with their great want of correct information. It is difficult not to see, that a great number of men, respectable for their position in society, cover the voice of philanthropy; men who see some philosophical incendiary in the attempts to enlighten the people who pretend to understand the usefulness of knowledge, and the perils of ignorance, and yet who, from trivial common place expressions, and by frantic, vain, half-instructed people, proclaim eternal war, not only against the misuse of instruction, but against instruction itself. The great majority of the people in several states of this union, are exactly of an opposite opinion, and those who know not how, know what they will, and that step is immense.—And whatever may be the situation of man, it cannot be inconvenient to uphold the justness of his mind, and the soft affections of religion and morality. It will be most an object to determine what knowledge is most useful to the people—we have already many notions about the kind of instruction they want. The only one that remains is the union of philanthropy and fact." We fear there is too much truth in the observations of this gentleman on the educational state of our country, especially when compared with his critical, just, and truly important views of the subject—but we would still hope that the vivid impression made on his mind from the great anxiety to have things as they should be, rather than as they really are, has led him to believe there is a greater degree of ignorance than there really is—we say this, for the honor of our country, hoping she will take every advantage of the lectures of a friend, who has not meant merely to censure, but to advise for the general weal.

In reference to the importance of educating the poorer classes of the youth of this country, your humble communicant, in mingling some of his own views with those of our traveller, believed to be specially suited to the circumstances in which we are placed, has the presumption again to appeal, through this more appropriate medium, to the farmers of Virginia, having some time since addressed them in vain, he fears, on the interesting subject—but he will now renew that effort with the hope that every succeeding year has rendered it more probable, that through a general advancement of society the subject of educating our poor youth in an especial manner, from both its propriety and necessity, will be discussed in our legislative halls, as not less important than the various internal improvements esteemed so essential to our prosperity; and if it can be proved that the success of our agriculture is intimately connected, and

*The time might be limited to eight or ten in this country.

much dependent on the improvement of the morals and intellect of the poorer classes of our population, there will be an abounding motive, a two-fold reason for snatching from the paths of ignorance and vice so large a portion of our fellow beings. Its peculiar and immense importance in our southern and western country is what will be chiefly dwelt on. The vital bearing it will have on the interests of the southern farmer, and planter, in keeping up the most careful and decided lines of distinction between the white and colored population, must be obvious to all reflecting persons; but perhaps there are too few who have traced to its ultimate probable termination the direful effects of permitting a considerable part of our white people to be abandoned to the society of the colored, who, from an awful necessity we are compelled to keep in a comparative state of ignorance; for which, we would ask the due consideration of all liberal and enlightened persons, and the forgiveness of that God, who we trust will recognize it as a necessary, though temporary evil, and expedient for the general preservation of good order and government, and the consequent aggregate happiness of society. It cannot be disputed, that the agriculture of our southern country has been, and still is, to a great degree, conducted by a class of persons (called overseers) whose information, habits, and manners, are ill calculated to advance the solid and permanent interests of the soil, but whose peculiar situation we will forbear to comment upon, (not being willing to wound the feelings of the least member of society,) further than to remark, that while the landholder has been engaged in dissipating his fair inheritance in a thousand different degrading ways, falsely called the generous flow of soul, his agent, has either been more than industriously engaged in supplanting him, or has been partaking of the same scenes of a lower grade, which has finally involved them both in utter ruin. If this picture is true to the life, how much will it become our farmers first to reform themselves, and then to pay a willing tribute for the education of the poorer classes? Sheer selfishness would dictate such a measure, if their sober judgment could be brought into free operation through the exclusion of ardent spirits and idle habits, and the adoption of temperate and industrious ways. Agents and sub-agents we cannot avoid, especially in our southern country, it will become us then, to make them faithful and intelligent, our own immediate interest, and that of the community is alike concerned. Who can doubt for a moment, the two-fold importance of training boys to the practical and laborious habits of agriculture, to become stewards and managers for men of landed property who cannot themselves go through the toil and attention requisite to its success—boys, who otherwise, perhaps, might have been tenants of a penitentiary, or dragging out a miserable existence under the pretence of following some half-learned trade, if any thing beyond a day laborer. To descend on the moral and political advantages attending a religious, and good English education, I leave to the immediate advocates of Sunday schools, temperance societies, and all such useful institutions. I will endeavor to urge something which may be practicable in relation to this kind of education, and as introductory to it, let the words of our late lamented Monroe bear witness: "I have no hesitation, however, in assuring you of my decided approbation of the plan suggested in your letter of connecting education with labor, with the view to improve the minds of our citizens and the agriculture of the state. By connecting them, many in the most humble walks of life will receive a good education, and be qualified for respectable stations, who would otherwise remain unlettered and ignorant. It is by extending information to the body of the people, that the best possible support will be given to our free system of government."

At the age of ten or twelve, when the labor of a boy should fully support him in a plain way, let as many youths be selected from districts of country, in such a manner as the legislature may direct, having

a teacher qualified to instruct them in all the necessary knowledge to be conveyed through the medium of the English language; an education which may be considered a good foundation for every useful occupation in life, not requiring a knowledge of the learned languages; an education which would not afford a favorable opportunity, to the development of such capacities and talents as would merit extension and patronage, from sources inviting to science and learning, where first impressions might be still further improved, and finally matured into character fitted for the most important trusts in our country. Their time should be divided between the labors, pleasures and amusements, in fact, and their routine of studies.—Their teacher, to be always with them, whether laboring or learning, save in the hour of free recreation if by experiment it should be thought necessary.—The teacher, as responsible for their progress in learning, would be, of course, tenacious of that portion of their time devoted to study, a sufficient guard against encroachment from another department. Exception may be made in favor of agricultural pursuits at particular times and busy seasons, by permission of the commissioners or trustees of such establishments. On the other hand, a farmer, selected for his general suitableness in the engagement should have the right to one-half of their time, directing their labors at his convenience and interest might dictate within the bounds of his farm as a remuneration for their food and clothing, which should consist of such as could be raised and made on the farm. A small expenditure for books, and the pay and board of a teacher, would be asked of a wise and generous government. Are there not many respectable men and good farmers, whose principles would induce them to adopt an expedient of this kind in preference to another mode of cultivation, more especially where a farmer has sons of his own to educate? It is not intended here to enter into a detail of any system, but merely to suggest, in plain language, an entire conviction, that a large portion of the poor youth of our country might be made mainly to educate themselves by their honest labor, in some judicious system, founded on the principles of the Fellenburg plan; in which their ultimate prosperity might be secured by the moderate contributions of the rich and middling classes; by some exertion of their talents and attention, first to procure the passage of the necessary laws, and then to see them executed.

To the adoption of some system of education, farmers and all others are earnestly exhorted, in the recollection that many of our revolutionary sages have pronounced that on the education of the present generation, depends the weal or woe of our commonwealths.

If the foregoing suggestions in relation to the union of education and agriculture should be met by any objections, it is hoped they will be, with the view of amending or substituting something better. Possibly it may be thought that this laboring class will be indisposed to the continuance of their industrious habits when they are of age and independent of any further restraint, because they are in possession of mental acquirements. Let it be answered that the very reverse must be the case, when exceptions are not made by an application of a different taste and inclination, through more than ordinary talents, to some other calling; because, their labor has been their pleasure and their bread; while their learning has been their meat and drink, and their delight, having been disposed to it, principled in it, and taught to venerate the plough, it will have become a second nature; and therefore, it is to be reasonably calculated, that the great majority of them will voluntarily pursue the mode of life they have been accustomed to follow. They will consequently seek employment in the agricultural line to the great advantage of landholders, and will, by the judicious application of their knowledge and physical powers, acquire, in a reasonable time, a better and more substantial foundation than three-fourths of our

professional men. What farmer, in his senses, would not prefer an aid or assistant (call them what you may, manager, overseer or steward) of good, industrious, laborious habits, with ability and knowledge in their business, to our present race of managers? Who will not prefer such, as agents, tenants, croppers, &c. and when they shall emigrate to new countries, they will carry with them the materials for good citizenship; be a credit and blessing to their newly adapted country, and never cease to remember the soil, and the circumstances which gave them respectability and honor among their fellow men. But, we believe, one of the most prominent advantages, especially in *Maryland* and *Virginia*, would be the successful application of their peculiar acquirements, to the restoration of tens of thousands of poor acres.

Perhaps, an inquiry may be made into the bearings and tendencies of this system of education—that it may have the effect of diminishing the value of our colored population.

Shall we regret the gradual exchange of so many degraded human beings, for a hardy intelligent race of freemen? If education can possibly have the effect of raising up one kind of population, and removing another, how gracious will be its operation. Africa's bosom is open to receive her sons. Who is there base enough, willingly to withhold the blessings of education from our poor white population, with the view of detaining longer amongst us the blacks? Who so vile, so little of a republican, to prefer a moiety of freedom to its full extension! None! Then all will lend their aid, to a discreet, prudent, and constitutional way of bettering the general condition of our common country, and particularly to rescue from ignorance the rising generation of poor, who are closely imitating the vices of the rich, rather than emulating their virtues. He is the happiest man who has a working hand, a thinking head, and a feeling heart. And let it not be forgotten, that our duty, and our interest, is seldom separated. But in the event of this system receiving public countenance, the question may very properly be asked, where are the teachers? The appropriate ones, alas! are not immediately to be obtained. Suffer then, this inquiry to inspire our young men to prepare themselves for the important task, for the honorable and useful vocation of teachers. Tens of thousands of dollars are annually paid the meritorious young men who emigrate here from our eastern schools and colleges, while other tens of thousands are yearly expended, worse than thrown away, by the dissipated youth of our land. This is a critical period in our history; few, very few, read, it is feared, with that attention and observation becoming men who should be looking forward to the excellency and prosperity of our institutions, through knowledge and virtue, rather than through wealth and influence.

But though we are restrained by an irremediable policy from the indiscriminate instruction of the people of color, we may nevertheless engage in Agricultural pursuits a limited number to be educated for the colonization of Africa. A sufficient education may be given them, fully to answer that purpose without the least expense to the country—from the age of ten years, they may be made not only to support and educate themselves, but lay up a handsome outfit for removal and settlement in Africa. This is a subject, too, which must be acknowledged truly worthy the deliberations of our state legislatures. It is high time for a people who have been so long drawing their chief support from the labor of others, to be willing to make some retribution.

O, my countrymen, look!—look at France! She, who so gallantly shared her blood and treasure with you, to secure your independence—behold her now, with reasons and motives, nothing to be compared to such as we can offer—removing, by the hundred, the barbarians of the North of Africa, to France, where they are to receive an education, which will best qualify them to be useful when they are returned to a work of reform in their own country. Glorious, gen-

erous, magnanimous people! This is a deed as far transcending the most splendid achievements of Napoleon, as the benignant rays of civilization and religion, transcend the splendid conquests of the ambitious conquerors of either ancient or modern times.

We think we see clearly in this transaction the progressive surrender of ignorance and vice, to intelligence and virtue—of Mahometism, to the spread of christianity. If this picture should be marred by any one saying, that France is interested in this act—we care not—but looking to the inevitable effects of such a measure will drop a curtain over some of the imperfections of our nature. So are we interested in the colonization of our negroes in Africa; but, we hope, for the charity of those who are not immediately connected with the subject, while the prosperity of two continents is promoted by the restoration of the original inhabitants of one of them. Can it be prudent to let time or opportunity pass by, in controlling by all other than arbitrary means every portion of the African continent, suited to the colonization of our free blacks?

(From the Genesee Farmer.)

RECLAIMING SWALE LANDS.

MESSRS. EDITORS:

Le Roy, April 12, 1853.

Your correspondent, J. M. S. inquires through the medium of the Farmer the best method of cultivating, or bringing too, low black ash land. Different pieces of such land may require different management. But most of such land is what is commonly denominated swamp, or swale land, and is made so by the obstruction of the water courses that receive the superfluous waters of the adjacent land. The timber having fallen for centuries across the natural and lowest passage for the water to pass off, the water has extended itself to various distances on each side, and formed a swamp, or swale, as it is more generally called, which is covered with water most of the year. By tracing this swamp or swale to its head, or source, most generally may be found springs of water, of some size, either open, or often concealed, by their source being blocked up by leaves, timber, &c. and the water having to make its way slowly by percolating and soaking through a large mass of matter that composes the swamp, keeping it at all times wet; and most of these swamps have a small descent, sufficient to pass off the water quickly, by merely removing the obstructions that have retarded its passage.

To cultivate such lands, the lowest part must be searched for and found, a sufficient ditch there made to carry off all the water quickly, and of sufficient size, particularly at its outlet, to carry the stream of water without any obstruction,—with side cuts to lead to the main ditch, wherever needed. The land will then become dry, and the timber may be cleared off without difficulty, and the land will be in readiness to receive timothy or redtop grass seed; and if the work is well done, a luxuriant crop of grass may be expected. Sometimes it will be the case, that in very extreme dry weather, before the muck or the vegetable matter that composes the surface be decomposed completely, it will dry up and the crop be light,—and if fire should get to it, the destruction of the surface is almost inevitable.

It becomes necessary, therefore, as soon as the roots are rotten enough to admit it, to plough and mix the muck with the earth beneath; and during this operation, the drainage ought to be consummated,—which may be, in the following manner:

Set a row of stakes at two or three rods, on each side of your ditch, for a guide,—plough to your stakes, by turning the furrows from the ditch, leaving the dead furrow at the ditch itself; and at subsequent ploughings, plough in the same direction, leaving the dead furrow at the same place, until a hollow be made sufficient to carry off the water. To prevent too great an accumulation of earth at one

place, increase the width of your ploughings (or lands) at each time.

By this method, a ditch may be formed that will not be liable to fill up by the treading of cattle. Carts can pass it with ease, water will flow up its sides, when high, and retire, when low, without doing any injury.

The remaining part of the swale may be ploughed in a contrary direction, leading the dead furrows to the main artery—and when finished in a workman-like manner, no water will stand in a puddle to stagnate, on any part of it. The most part of the work may be done with the plough, and in preparations for a crop, leaving but a little to be done in the cross ditches near the main one,—to be thrown out by the shovel, or to be leveled with the hoe.

I once had a very low piece of black ash swamp, on which, before I commenced upon it, the water stood, nearly all the season, about knee deep,—a real musketoe, fever and ague hole,—a receptacle of all uncleanness. I cleared the timber from it, made a ditch and sowed it with grass seed. When the roots of the timber became a little rotten, in October, I commenced ploughing it, burning the stumps and old logs as I went. The following season, and during the summer, when the muck was too moist to burn, but not too moist to plough, I finished my ploughings, got it in fine order, and the first week in September I sowed it with wheat and seeded it again to grass,—and although it was my first attempt, and the drainage not perfectly done as it might have been, and although the fire had got in, the previous season, and done some damage, I obtained rising of thirty bushels of wheat to the acre,—and should have got more, had not a good deal of it been lodged down.

T. T.

(From the Genesee Farmer.)

AGRICULTURAL IMPROVEMENT—AGRICULTURAL SOCIETIES.

Rensselaer county, April 23, 1853.

In a former number I endeavored to show that the improvement of agriculture and the present generation of operators was to be effected, or an impulse given to produce that effect, firstly, by the distribution of agricultural papers. I shall now endeavor to show that it is to be accomplished, secondly, by the formation of agricultural societies. That the united exertions of an organized body can accomplish more and bring about results sooner than that of individuals, is a position that will probably not be controverted.—Else, why do men associate to promote the great objects of benevolence and humanity? Why are associations formed for the distribution of the Bible? Why have we Missionary, Colonization and other Societies? Why is the world moved as it were in a body, on the great and important subject of Temperance? Who, but believes, that more has been done within the last five years, towards destroying and ridding the world of that hydra, intemperance, by the formation of national, state, county and town societies, than could have been accomplished in half a century, by the insulated exertions of humane and philanthropic individuals? Organized associations, act as a grand lever upon public opinion, which must be moved before any great public object can be accomplished. Why not then, if we gain so much power, and so great an advantage is to be derived from them—encourage and establish societies for the promotion and improvement of agriculture and the mechanic arts? None will deny their importance—none their need of improvement. Let societies then be formed in every state in the union, in every county in each state. Let them be managed principally by practical farmers. Hold out inducements to excite a spirit of inquiry, and of emulation in all the various branches of husbandry, and the mechanic arts. Let our farmers associate and interchange sentiment—let each profit by the experience of all the rest, and soon,

the face of the country will be changed—soon will our productive valleys double their increase—our barren plains become fertile, and the “wilderness blossom as the rose.” Nor will its effect be less visible upon the moral and intellectual state of our yeomanry.—The first and best employment of man, will soon be regarded as honorable and pleasant, as it has been wont to be considered mental and slavish. Mind will range the sylvan scene, and men’s highest ambition will be to excel in the application of science and the production of successful results. Honor’s alluring wreath will encircle the brow of him who shall produce the greatest results with the least expense.—Improvements in the implements of husbandry will follow. Labor saving machinery, be introduced and adopted. The mind will aid the hand, and our country exhibit one continued scene of improvement, happiness and prosperity.

But there are no doubt many who will say these are the dreams of a visionary—the vagaries of a wild and distempered imagination. In answer, I say, let me call your attention to those countries in Europe where agriculture is patronized, and where societies are formed for its promotion. Turn your eyes to those districts in our own country where societies have been established, and compare them with those that have none—are not the same results produced as above stated? The moral and intellectual condition of the people improved—the state of agriculture from thirty to fifty per cent. advanced—and the value of the soil correspondingly enhanced. Our state society has been organized but a year, and already do we see and feel its influence—its branches are extending far and wide. Jefferson county has long had her society, as her improvements bear ample testimony. Oswego, Monroe, Onondaga, Saratoga, Columbia, Clinton and Essex have recently organized societies, and I hope the day is not distant, when every county in this state, at least, will do likewise. Let us go on then heart and hand, put our shoulders to the wheel and forward that which tends to so much usefulness. Let us emulate those that have preceded us in disseminating knowledge—ameliorating the condition of man—and spreading the blessings of Providence in such profusion.

VOLO.

(From the Genesee Farmer.)

PERMANENT PASTURES.

Some of the old fields of the Genesee country, which have been cleared more than thirty years, and which might produce excellent crops of wheat,—have never yet been disturbed by the plough. I believe these are generally kept as pastures; and some of our best farmers consider them more valuable than any other lands of equal quality which have been laid down to grass. On my farm, I have one field yet remaining in this condition; and the question has been several times agitated, whether we ought to plough it up, or not? The point is not yet determined.

To the rich vegetable mold near the surface, is ascribed the peculiar productiveness of such lands; and in a note to the American edition of “The Code of Agriculture,” the writer asks, “If when a rich surface has been got, should it be destroyed?” This is the very question also, which I wish to ask.

Sir JOHN SINGLAI, although he thinks “It is often desirable to keep one or two inclosures in *perennial pasture* for feeding sheep and cattle; yet his regard for *old turf* or *permanent pasture*, is not so great as that of some other writers.” On this subject he makes the following remarks:

“The principal objection to the conversion of meadow into arable land, arises from an alleged inferiority in the new, when compared to the old herbage; a complaint which probably originates, either from the improper choice of seeds, or from giving them in too small quantities, thus favoring the growth of weeds. A gentleman who had a large farm, principally consisting of strong rich clay, (every field of which, with hardly an exception, he occasionally broke up,) was

accustomed to lay them down with a crop of barley, and to sow fourteen pounds of white clover, a peck of rib grass, and three quarters of hay seed per acre. By this liberal allowance of seed, he always secured a thick coat of herbage the first year, which differed from old pasture, *only in being more luxuriant*.”

LORAIN, in his observations on the agriculture of England, evidently considers this partiality for old pastures as an unfounded prejudice. He says, “The landholders of Great Britain, would have long since seen the value of convertible husbandry, had not their judgment been blinded by the imaginary value of their old grass grounds; for they consider submitting them to the plough, little less than sacrilege; and it appears that the opinion is not confined to men of contracted sentiments.

“When grounds become matted with the roots of old grass plants, it does not appear reasonable to suppose them capable of producing crops that will bear any tolerable comparison with those gathered from grounds of equal quality, which have been recently laid down with the best artificial grass seeds; for the roots of these young plants are healthy and vigorous, and capable of pressing forward in search of nutriment through a soil which being free and open, admits a ready passage for them in every direction.

“It should be laid down as a *maxim* in farming, that no grounds should continue in grass, until they become hard bound or consolidated; and the roots become old and matted.—Great crops of grass, can be no longer obtained than while the soil continues free and open, and the roots remain unimpaired.—If one-fifth part of those lands were annually cultivated in summer fallow crops, and another fifth part in grain, the remaining three-fifths would produce more grass than the whole while lying in old pastures.

“Why, then, should enlightened cultivators dread the effects of the plough on their grass lands?”

In some future paper, I intend to give a different view of this subject, and in the mean time I hope some of your correspondents will favor us with their remarks.

A FARMER.

(From the Genesee Farmer.)

LEACHED ASHES FOR MANURE.

MESSRS. EDITORS:

Potter, April 13, 1833.

Many years ago I was on a visit to an uncle of mine on Long Island. A man brought a load of wood, corded it at the landing, and applied for a load of leached ashes, (fourteen bushels,)—he received them, and paid my uncle four dollars. I remarked, that the man could never see his money again, if he used them as manure. My uncle replied, I know not how it is, Richard, but it is certain *that we grow rich by it*. This short observation, I think, contains more of argument than even Dr. Mitchell could have given us in volumes of theoretical reasoning.

It was the result of experience, and I know of many thousand acres on the island, which were once too poor to produce even mullens and rib-grass, which now cut from one and a half to two tons of clover hay per acre; and this has all been done by buying leached ashes at from twenty-one to thirty-two shillings for fourteen bushels, and carting them from one to ten miles.

I therefore conclude that leached ashes are a good manure, and if properly applied, will be found invaluable even in western New York. The modes of using them are various, and may be the subject of a future communication. Yours, etc. R. M. W.

(From the Maine Farmer.)

MR. HOLMES:—I wish to communicate to the public through your paper a new and very expeditious method of “harrowing in” the English flat turnip seed. Sow the seed in the usual manner—then turn your flock of sheep into your yard and drive them round for a few minutes, just enough to give them a little exercise, and the work of harrowing is done.

Yours, &c.

FLAT TURNIP.

HORTICULTURE.

(From the Genesee Farmer.)

PRACTICAL HINTS.

Young says, “the undevout astronomer is mad.” This remark, may well be applied to the Farmer and Botanist. The plants we cultivate, disclose to the enlightened mind, a thousand wonders unobserved by the ignorant. They open a field for rational contemplation and innocent pleasure, well fitted to improve the understanding, to refine the feelings, and to elevate the soul to a holy intercourse with our Maker.

God may be seen in the garden and in the field; and here we may walk with him, as well as in the sanctuary. The farmer, who is unobserving of these things, and pursues his labor without ever raising his thoughts to the Author of all good, loses the richest and noblest pleasure, which his employment affords.

My present object is to make a few remarks on vegetable physiology, which have been a source of pleasure and profit to myself, and possibly may be to others.

In our fields of corn, we behold the blade ascend, and the ears fill with grain; and in the course of a single season, several tons, on a single acre, are elevated above the surface; and in our forests, where this process has been going on for a succession of years, we behold hundreds of tons, thus raised, particle by particle, from the earth. Here is an exhibition of power, which invites our investigation, and the inquiry naturally arises how this matter is elevated.

Some may say that it is alone by the immediate power and agency of God, by a kind of continued creative effort. But God, so far as we can observe, operates by second causes, or through the instrumentality of means, and to refer the matter to the immediate power of God, leaves the matter unexplained.

Another says, vegetables are expanded and elevated by *capillary attraction*, that is by the attraction which causes fluids to ascend in a sponge or a heap of ashes. But water will never ascend in a sponge higher than the upper surface, and by this power, it is obvious that a vegetable could never ascend above the surface of the earth; or suppose it to have attained a given height, it could never rise higher.

We must therefore look for some other power continually exerted to push the plant upward to its destined elevation. This power we find in *heat* by reason of its expansive influence on fluids. The sap is supposed to ascend through the pores of the plant, as the mercury ascends in the tube of the thermometer, by the expansive power of heat.

The whole albumen, or white part of the wood of a tree next the bark, consists of an aggregation of pores or small tubes closely combined; and the heat which expands the ascending fluid, contracts the tubes in which it ascends. The solid part of the tree is indeed expanded, and the obvious effect of this will be to contract the cavities of the tubes which it contains. If the tube and the ascending fluid were expanded alike, there would be no ascent of sap.

That sap ascends, and the plant is expanded and pushed upwards by the expansive power of heat, is fully confirmed by the experiments of Mr. Hales.

This gentleman, after cutting off grapevines, closely fitted upon the stumps glass tubes. In these, as soon as the morning sun began to give its warmth, the sap began to ascend, and continued to ascend through the day till the heat began to abate, when it again subsided in the tubes. When a cloud obscured the sun, it would sink. These tubes which were placed many feet above the earth, sent up the sap much higher than those which were placed near the earth. The reason evidently was, that the former had a length of body admitting of a greater expansion than the latter.

From these facts we see the wisdom and goodness of God, in the alternations of cold and heat. In the heat of the day the sap ascends and sends up the stalk; at night the sap descends, and the earth, being

warmer than the superincumbent air, the sap is propelled through the roots and causes their growth and expansion.

In the cold and wet seasons, which we sometimes have in May and June, the blades of corn turn yellow and their growth is apparently checked. This I formerly witnessed with some impatience, but I have become quite reconciled to it, from the belief, that while the growth of the blade is checked, the root is growing with perhaps unusual rapidity.

Without an interchange of cold and heat, vegetation is feeble and sickly. Moist and hot weather we know is favorable to vegetation; but when this is long continued, the stalks of grain become feeble and tender—hardly able to bear their own weight.

I remember well such a season, when flax and oats, which for a while gave unusual promise, afterwards fell by their own weight and gave a very indifferent crop. Such was the effect of long continued hot weather on the wheat crop in 1831.

The stalks and roots of plants act reciprocally upon each other. The root sends up sap to nourish the stalk; the stalk returns the sap to nourish the root. The seed when committed to the earth first sends forth the root, and the root, when it has attained a moderate extent, returns the sap to send forth the blade.

In our perennial plants and trees, the root is the reservoir for the future growth. By the growth of the summer the powers of the root are exhausted; and again by the descending sap of autumn the root is replenished.

Hence we see why a too liberal pruning, when the foliage is in its greater vigor is injurious. It deprives the root of its resources.

Hence we see also, why our cultivated grasses are sometimes injured, when mowing is immediately followed by close feeding the after growth. The root is injured because its exhausted energies are not renewed by a subsequent growth.

Those grasses are most injured by mowing and feeding, whose leaves are chiefly upon the stalk, as timothy and red clover. Those are least injured whose leaves spring chiefly from the root, for instance spear grass, red top and white clover. These latter grasses, having their leaves near the ground, cannot be so much injured by the scythe and feeding, but that they will survive while other grasses die.

Every much question, whether good policy would justify our suffering an animal to go into our mowing lots, except to remove the hay. At any rate they should not be put in, till late in October, when the after growth has attained full size, and the roots of the grass are replenished.

Hence as we see, why bushes and weeds may be killed by cutting, when their vegetation is most perfect. Bushes should be cut in the latter part of August before the descending sap of autumn begins to replenish the root, that is, just before the commencement of cold nights when the leaves begin to turn yellow. Weeds should be cut just before the seed comes to maturity. The Canada thistle, if cut at this time, and the subsequent growth prevented, is as easily subdued as any other plant. Repeated experiments justify me in this assertion.

The roots of esculent plants, such as beets, turnips, onions and potatoes, it is well known, receive their growth from their tops. The unripe onion continues to grow for weeks after it is pulled. Potatoes of considerable size may often be found growing out of the stalk, when it has been pulled and laid upon the ground in its unripe state.

We also hence learn the impolicy of cutting the tops from corn before it ripens. The trifle you gain by cutting them, you take from the ripening ear. I once cut a few hills when the green corn was just fit for cooking. The grain apparently grew but very little afterwards, and shrunk to half its size.

I throw out these hints, hoping that some more able pen will give us a more full and perfect account of the vegetable economy. E. D. ANDREWS.

(From the Genesee Farmer.)

HORTICULTURE.

We perceive an increasing liberality of opinion among our farmers on the subject of gardens, and more especially of flower gardens. This is in the exact order of nature. The adventurous yeoman who pitches his tent in the wilderness, will be engaged in more important concerns than cultivating flowers, necessity being the first law. The forest must be subdued; provisions for his family, and fodder for his cattle, must be provided; and when, after his crops are secured by good fences, and the winding path among the trees, is deserted for the regularly laid out highway, there are houses and barns to build, and to pay for, before the frugal husbandman allows himself much of the luxury of congregating the beauties of nature. Ornamental gardening belongs to the last class of rural improvement. "When ages grow to civility and elegance," says Chancellor Bacon, "men come to build stately sooner than to garden finely, as if gardening were the greatest perfection."

When we have heard, therefore, the question in reference to flowers, "what are all these things good for?" expressed in the tone of indifference or contempt, it has excited in us no surprise. Many of our farmers have carved out their own fortune with hard hands. Habits of frugality so long persevered in, continue, in men of a more rigid fibre to operate when the necessity no longer exists; and like the planetary bodies, they retain their *momentum*, and roll on in their old orbits. Of such, however, (whom we think are only a small minority,) we will take the liberty to ask in turn, what is any thing good for, but as it conduces to our pleasures and our comforts? Objects may give us pleasure which we neither eat nor sell; and those who are the *most saving*, indulge in many such luxuries. We wish them to reflect a little more on this subject; and if their wives or daughters want flowers in the garden, indulge them—it will cost but little, and may gild many a leisure moment.

Our main object, however, at present, is to recommend the kitchen garden; and to induce our farmers to raise a greater variety of good things for their tables. Cabbage, and potatoes, and beets, and parsnips, are all excellent,—we could by no means do without them,—but some kinds of cabbage are better than others, as well as some kinds of beets, or of potatoes. Try different kinds and find out the best. Differences of taste render it proper that each should examine for himself.

A few years ago cauliflower and broccoli were very rarely cultivated in the Genesee country; and we remember to have heard the idea advanced that none but a skilful gardener could produce them. It is not so—they require no more skill than cabbages do.—Our first attempt at growing them, happened in an old barnyard where manure was most plentifully mixed with the soil, and our success was eminent, for plants of this kind, are *course feeders*. Many of our neighbors had never seen such things; but from that time down to the present, these have ranked among our *indispensables*.

We must bring our introduction to a close however, in order to make room for the following paragraphs, taken from the *Memoirs of the Philadelphia Society for promoting Agriculture*, volume iv. It was from the pen of Judge PETERS, and appears in the index.

"Horticulture is mentioned, not for reference, but most serious regret. No communications appear in our volumes on this subject. And yet the management of a KITCHEN GARDEN, as it is called, is of the first importance to every farmer; and is most lamentably neglected. Few of our farmers sufficiently attend to their gardens; and too many neglect them entirely. If more vegetable food, and less flesh, were consumed on our farms, the more health and comfort would be the results. Nor would economy in our domestic affairs, be found the smallest consideration. The cheap luxury of garden fruits and vegeta-

bles, the innocent employment of time, and the health insured by them, ought to be incentives to a most careful and intelligent attention to their culture."

RURAL ECONOMY.

(From the Genesee Farmer.)

ON THE USE OF SALT

AS A CONDIMENT FOR DOMESTIC ANIMALS.

Although salt is not indispensable to human life, it is indispensable to the comfort and health of man. It is not convertible into nutriment, but is a strong stimulant to the animal fibre. We are not satisfied with its occasional use, but desire to have it blended in every meal of which we partake. Most quadrupeds, and particularly domestic breeds, have a like fondness for this condiment, and its use is probably as grateful and beneficial to them as it is to us. And why should not the *daily* use of it be extended to them? From some years' experience, in which salt has been daily accessible to my neat cattle, I am induced to believe, that this is far the best way of administering it. I have salt troughs under my sheds, in which there is a constant supply. The cattle never take it in excess, and consume very little more than when I gave it to them but once in a week.

I apprehend the importance of this condiment to farm stock has not been sufficiently reflected upon, or properly appreciated, by the generality of our farmers, particularly as a means of preventing, and often of curing diseases. I will therefore cite the practices of different countries and individuals, as calculated to afford useful hints to your readers upon this subject.

In Bengal, a *daily* supply of salt is given to the shepherd to feed his sheep, and the mutton fed in this way is finer than any other killed.

Lord Somerville restored the health of a large flock of merinoes, which had become quite sickly, by giving them salt *twice*, and sometimes *thrice* a week. He gave a ton of salt to a thousand sheep during the year. He says they require most in spring and fall, when the dews are heavy.

In Spain the shepherd is furnished with twenty-five quintals of salt for every one thousand sheep, which they consume in five summer months, not being fed with it in winter, or on their long journeys.

Mr. Curwen gave four ounces per week to each sheep, at two feedings of dry food, and when fed with turnips he says it should be fed to them without stint.

Arthur Young says, sheep should have as much salt as they will eat.

Lord Somerville, Mr. Young and Mr. Curwen, unite in urging its use as a preservative against the injurious effects of moist and wet situations. Mr. Curwen's flock was attacked by an inflammatory disorder; he gave them a considerable quantity of salt, and the disorder was immediately stopped by it.

On the farm of Mr. Mosselman, in the Netherlands, says Sir John Sinclair, the rot in sheep was effectually cured by the use of salt.

Mr. Bracebridge drenched his sheep affected with rot, night and morning, with strong brine, after which he did not lose one.

In Sweden, Saxony, Silesia and France, salt is given to sheep. They require it most when languid, or out of order, which happens in fogs, in heavy rains and snows.

Charles Adams used salt for ten years, as an antidote and cure for diseases; and in all cases of diarrhea. He gave three and a half drachms, in a dry state, introduced with a spoon into the mouth, and holding the chops a few seconds till the salt dissolved.

Cattle and horses are far less liable to disease in America than in Europe; and this is believed to arise in a great measure from the more free use of salt here than there. The duties upon this article in Great Britain,

for home consumption, until recently, have been so enormous, as in a great measure to preclude its being used for cattle. The bill of the cattle doctor has formed no inconsiderable item in a British farmer's expenditures. Here such expenditures are almost unknown. In the year 1822, says Mr. Curwen, *before I commenced giving my cattle salt, my farrier's bill averaged fifty eight pounds per annum, or more than two hundred and fifty dollars; and since I have commenced using salt I have never paid in any one year over five shillings.*

In the district of Champseau, France, and the adjacent countries, they were in the habit of giving every ox and cow four ounces of salt every eight days. When this practice is neglected, the animals eat less; they lose their spirits, their hair rises, they go licking in their stalls where the salt-petre is formed, they grow lean, become barren, and disease ensues.

The French Royal Academy of Science state in their memoirs, that salt augments the nourishment of the food of cattle, in proportion to the quantity given; that no ill consequence will follow from excess, even though it should be given them without stint.

It is a practice in our southwestern states, in travelling, to give horses solid food, with a handful of salt twice a week. A friend of mine lately performed the journey from St. Louis to Albany, on horseback, at the rate of forty to forty five miles a day. The horse was in good condition at the end of the journey. His almost only feed, west of the mountains, my friend informed me, was half a bushel of oats, and a little salt, placed in his manger each night.

In Germany, according to Count Rumford, salt is universally given to cows and oxen in a fattening state, and their fattening powers are found to be in proportion to the quantity given.

In Bengal fattening bullocks receive a daily supply of salt.

Sir Thomas Bernard kept a lump of rock salt in the mangers of four horses, spring and autumn, several years, the effect of which was, that three of the four horses were in good health, with very little exception, for fourteen years. The same gentleman says, that salt is given to animals when greater exertion is required of them; and that in the east, the camels are allowed salt during the passage of the caravans over the desert, as a support in the extreme they undergo.

Vailey, in his Farmer's Guide, says that a poor torn down horse, put into a salt marsh, is purged and cleared of every disorder, and immediately becomes fat.

Curwen, in his evidence before the House of Commons, considers salt indispensable to the health and thrift of animals; and that the first visible effect of salt to milch cows, was in its *freeing the milk and butter from all taste of the turnip.* My cows have been fed with turnips, spring and autumn, for ten years. They have always access to salt. I never experienced any inconvenience from the turnip taste in the milk and butter. I never conjectured the cause until I read the testimony of Curwen, above quoted. He latterly gave six ounces *per day* to his work horses, four with steamed potatoes, and two with steamed chaff. The following shows the quantity *per day* given to his stock, which he commenced with in April, 1818, and to which it had been beneficially increased in December, 1819.

April 1818. Dec. 1819.

	oz.	oz.
Horses,	4	increased to 6
Milch cows,	4	4
Feeding oxen,	4	increased to 6
Yearlings,	2	3
Calves,	1	1

A very common method of giving salt to stock, with us, is to mix it with the hay, when housed. It not only affords, in this way, a condiment to the animals, but tends to preserve the hay from injury when not perfectly cured. It is also applied to dry hay, straw and corn stalks, in winter, in the form of brine.

From these quotations, which might be greatly multiplied, I am confirmed in believing the mode I have a long time adopted to be the best, that of giving animals access to salt every day. This I do by fixing troughs under my sheds, in which salt is constantly kept. To prevent waste, a few slats may be nailed crosswise, at ten or twelve inches distance. I have seldom had a sick animal during the continuance of this practice. (See an interesting publication on the use of salt by Rev. B. Dacre, J. L. S. 1825.)

(From the Genesee Farmer.)

BUTTER.

This is one of the staple productions of our state; and every hint that serves to improve its quality, or increase its quantity, must be useful. There are various methods of making butter, as from new milk, lobbied milk and cream; and there is certainly a great diversity in its quality. The cause of this difference may partially be owing to the season, the feed and the breed of cows, but most is owing to bad management. Our dairy women are very much like their good husbands, apt to be somewhat conceited, too wise to learn, and generally believe their own mode the best, and never suspecting that philosophy or science can have any sort of connection with this humble branch of household labor. All seems to be agreed, however, upon the following points.

1. That cleanliness is the first requisite, for many and very obvious reasons.

2. That every sort of liquid should be separated from the butter—because if such is suffered to remain it soon becomes rancid, and tints the mass.

3. That the salt used to preserve it should be pure, because bad salt will not keep it sweet—rock salt, and that produced by solar evaporation, being deemed best.

4. That no more salt be used, than is necessary to render the butter palatable—all excess being injurious to the taste, and an imposition upon the buyer.

5. That the vessel in which it is packed should be incapable of imparting to it any bad flavor—wood abounding in pyroligneic acid, and red earthen being improper—the first giving a bad taste, and the latter, by reason of the decomposition of the glazing, which contains lead, being in a measure poisonous.

6. That when packed, the external air should be wholly excluded from the butter—because the air soon induces rancidity.

My dairy woman has added two other rules, which she deems all important to the preservation of good butter, but which I am induced to think are but little known and less practiced, viz:

7. That no water be suffered to come in contact with the butter in any stage of the process—because it tends to lessen the essential volatile matter which gives to butter its rich peculiar flavor.

8. To have the salt incorporated with the butter in the first operation of working, and after an interval of twenty-four hours, to apply again the butter ladle until the whole of the liquid is expelled. By this operation the salt is dissolved and effectually blended with the butter, which is freed more effectually from buttermilk.

I sat down to write merely an introduction to two tables, which I am about to copy, and which indicate the temperature at which cream may be most advantageously wrought into butter. It may be said that these will serve but little purpose, as a thermometer is seldom seen in a dairy house; yet it will show the importance of keeping one. A thermometer will cost two dollars, and I apprehend that its advantages will soon repay cost, in the dairy alone.

The Highland Society of Scotland offered a premium on experiments on the temperature at which butter can be best procured from cream. The following tables show the result of a part of these experiments. The detail may be found in vol. vii. of the Society's Transactions, p. 194 to 201.

Number.	Date of experiments.	Number of gallons.	Mean temperature.	Time occupied in churning.	Quantity of butter obtained.	Quantity of the churned milk.
	1825.			h m	lb. oz. diet.	lb. oz.
1	Aug. 18	15	55°	1 0	1 15 7.5	8 9
2		26	60°	3 15	1 15 3.2	8 8
3		30	62°	3 0	1 14 0	8 8
4	Sept. 4	15	61°	3 1	1 12 12.7	8 8
5		9	70°	2 0	1 10 10.6	8 7

OBSERVATIONS.

"The butter produced in the first experiment, was of the very best quality, being rich, firm and well tasted.

The second experiment yielded butter of a good quality, and not perceptibly inferior to the former.

In the third experiment butter of a good quality was obtained, but of an inferior consistency.

The fourth experiment produced soft and spongy butter.

The butter produced in the fifth experiment was decidedly inferior in every respect to any of the former specimens."

Number.	Date.	Heat of the cream.	Scotch pints of cream.	Degrees of heat when butter came.	Quantity of butter, lb. oz.	Time of churning.	Weight of cream.	Heat of air at 8 p.m.
					lb. oz. h. m.			
1	June 13	56	16	60°	16 8 1	20.4 to pt.	56°	
2		20 52	16	56	16 0 2	do	52°	
3		21 52	16	56	16 0 2	do	52°	
4	July 12	63	16	67	15 8 0	30.3 "	14 70°	
5	Oct. 20	50	16	52	15 12 3	0 4 "	1 50°	
6	Aug. 20	53 1	16	57 1	16 3 1	15.4 lbs.		

No. 1, shows the greatest quantity of butter produced by the above heats.

No. 2, the best quality of the butter.

No. 3, the fine flavor and quality of this butter could not be surpassed.

No. 4, the quality soft, white and milky.

No. 5, quality injured by long churning.

No. 6, quality most excellent, high in color and flavor, and solid as wax.

From the experiments, as shown in both tables, it would appear, that the proper temperature at which to commence churning butter, is from 50 to 55 degrees, and that at no time in the operation ought it to exceed 65 degrees, or fall below 50 degrees.

(From the Genesee Farmer.)

INTERESTING EXPERIMENTS.

In the January number of Sullivan's Journal, in an article translated from the *Bibliothèque Universelle*, is given the results of some experiments performed by the celebrated agriculturist Dr. Dombasle for determining the relative nutritive value of the aliments of sheep and cattle. An abstract of the article is here given.

Forty-nine sheep were divided into seven lots, of seven sheep each, in such a manner that the total weight of each lot should be, as nearly as possible, equal to each of the rest. Each lot was kept in a separate division of the stable, the food was given to each lot in rations of equal weight, and by means of scales, the total weight of each lot was taken once a week, and the experiment was continued five weeks. The weight of each lot was four hundred and thirty-six pounds.

The substances subjected to examination were: 1. Dry lucerne. 2. Oil cake from flax seed. 3. Oats and barley. 4. Crude potatoes. 5. Cooked potatoes. 6. Beets. 7. Carrots.

One of the seven lots was fed exclusively on dry lucerne, of which fifteen pounds were found to be a proper ration of one sheep per week. Each of the

six others received just half the quantity of lucerne, or seven and a half pounds, and the remainder of the ration consisted of such a portion of the other alimentary substances, as was found sufficient by a careful weighing during the five weeks, to keep each lot in the same healthy condition. Of these substances, the following quantities were found to be equivalent in nutritive value to the half ration of lucerne.

Oil cake,	44 lbs.
Barley,	34 "
Oats,	5 "
Crude potatoes,	14 "
Cooked potatoes,	13 "
Beets,	16 "
Carrots,	23 "

The quantity of water drunk by each lot of sheep, measured by a gaged trough, during the five weeks, was as follows, showing the relative degree of thirst occasioned by the different aliments.

1st lot, 223 quarts.	5th lot, 108 quarts.
2d " 189 "	6th " 95 "
3d " 164 "	7th " 86 "
4th " 123 "	

Prices Current in New York, May 25.

Beeswax, yellow, 18 a 20. Cotton, New Orleans, 12 a 15; Upland, 11 a 13; Alabama, 11 a 14. Cotton Bagging, Hemp, yd., 13 a 24; Flax, 11 a 15. Flour, American, 8 1/2 a 9. IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals, viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	300
Do 2 " " Do "	250
Do 1 1/2 " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each.

Half Blood and upwards.—A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenth Durham Shorthorn, very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$100.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address I. I. HITCHCOCK.
Amer. Far. Office.

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale. Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life.) is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also,—A young JACK, a son of Don Carlos, 4 years old, 43 inches high, well made, stout and promising, of same color as his sire—price \$200.

Also,—A full sister of the last, 3 years old, 44 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

I. I. HITCHCOCK,
Amer. Farmer Establishment.

Ap. 26—tf.

TWO IMPORTED MALTESE JACKS FOR SALE.

These animals were purchased in Malta in June, 1832, for two officers of the U. S. ship Concord, in which they were imported. The selection was left to one of the best judges in the island, who advertised three months previous to purchasing, for the largest and best bred Jacks, without regard to cost—more than one hundred were offered before a choice was made. They are now about three years old, and stand, one 13 1/4 and the other 13 1/2 hands high, and will yet grow three or four inches: their color is black with fawn nose, eyes and belly. In size, action and vigor, they were believed to be unsurpassed by any Jacks in Malta, and they have been pronounced by good judges, the finest ever brought into the United States. It is deemed unnecessary to say any thing about the superiority of the Malta Jacks; it being well known that they are of the high bred stock of Persia and Arabia.

These animals may be viewed and every information respecting them, may be obtained, by applying to I. I. Hitchcock, American Farmer establishment, Baltimore. The price is \$600 each.

TO VINE DRESSERS.

The Subscriber wishing, to engage a Vine Dresser to take charge of a flourishing and fruitful Vineyard, offers the most favorable terms to a person who can furnish testimonials of a good character.

For particulars apply to I. I. HITCHCOCK, American Farmer Establishment, or to the undersigned by letter, addressed to Brown's Mills, Mullin Co. Penn. May 24. tf. JOSEPH HENDERSON.

CHOICE MERCER POTATOES FOR SALE.

I can furnish a small quantity of Mercer Potatoes of superior quality for seed, at 75 cents per bushel.

I. I. HITCHCOCK,
American Farmer Office and Seed Store.

TO FARMERS

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Scythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

HARVEST TOOLS, WHEAT FANS, &c. SINCLAIR & MOORE, have in store, and are manufacturing a general assortment of HARVEST TOOLS, among which are

100 WHEAT FANS, double and single geared.

300 Grain CRADLES, with Scythes complete. This article is made of the best and most durable materials, and will be warranted as such.

50 doz. Grass and Grain SNEATHS.

30 doz. Hay and Manure FORKS.

30 doz. RAKES and Wooden tined FORKS.

SCYTHES and Sneaths, bung ready for use.

SICKLES, English and American Seythe Stones, Strickles, &c. &c.

Their Stock of CASTINGS, Agricultural Implements, Garden Tools and SEEDS, is as usual full and complete.

Also, just received from Europe, two bales, containing Lucerne and Ray Grass, Cabbage, Radish, Lettuce, and many other valuable SEEDS of last year's growth. From the appearance of this lot of Seed; and the respectability of the establishment from which they were imported, they can with the greatest confidence recommend them. May 24.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—There is very little variation in the price of any article from our last quotations. Wheat is the only article that has varied, a slight decline having taken place in it. The wagon price of Howard street flour continues at \$5 25 a 5 37 1/2.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do, ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 6.00 a 20.00.—Line yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Bappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 635 hlds. Md.; 188 hlds. Ohio; and 6 hlds. Ken.—total 829 hlds.

FLOUR.—best white wheat family, \$6.75 a 7.25; super Howard-street, 5.50 a 5.62 1/2; city mills, 5.75 a —; city mills extra 6.00 a —.—CORN MEAL bbl 3 62 1/2.—GRAIN, best red wheat, 1.17 a 1.22; white do 1.26 a 1.30; —CORN, white, 62 a 63; yellow, 63 a 64; —Rye, 70 a 72 —OATS, 37 1/2 a 41 —BEANS, 75 a 80 —PEAS, 65 a 70 —CLOVER SEED 8.00 a ——TIMOTHY, — a ——ORCHARD GRASS 3.00 a ——Tall Meadow Oat Grass 2.00 a 2.50.—Herd's, — a ——Lucerne — a 37 1/2 lb —BARLEY, —FRANSE 1.50 a 1.62 —CUTTER No. 11 a 13—LON, 12 a 14—Alab 11 1/2 a 13—Tenn. 11 1/2; N. GENERAL

Agricultural and Horticultural Establishment; COMPRISING,

A Seed and Implement Store, a General Agricultural Agency, and the Office of the AMERICAN FARMER, at No. 16 South Calvert street, Baltimore: in connexion with a Stock and Experimental Farm, Garden and Nursery in the vicinity.

✂ An extra number of the Farmer, containing a prospectus of the "Establishment," and a "Catalogue of Seeds," &c. kept for sale, shall be sent GRATIS to any person who shall by mail or otherwise furnish his address for that purpose.

AGENTS FOR THE FARMER.—All postmasters are requested to act as agents for the Farmer, and to require a strict compliance by subscribers with the terms, especially the third item. They are authorised to retain one dollar for each new subscriber, and ten per cent on all other collections. The list of special agents is published in the Farmer every third week. (Terms next week.)

✂ DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "I. I. Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

AGRICULTURE.

DEEP PLOUGHING.

The following article from the Maine Farmer, will be read with interest, as the propriety of deep ploughing is discussed with considerable ability. Both parties to the discussion evidently understand the subject practically, and the arguments of each would seem to be conclusive. Yet (if we may be permitted to interfere in the controversy) we think that the theory of each may be modified, and thus made to meet the ideas of both. We would suggest the modification as follows: We think that deep ploughing is generally injurious; also that shallow ploughing is equally so. Deep ploughing buries the nutritive matter of the soil so deep that the sun and air cannot act upon it, and its virtues are, therefore, lost to the crop, till a subsequent deep ploughing brings it again to the surface. It also buries the seeds of weeds, &c. so deep that they cannot vegetate till returned to the surface by a subsequent deep ploughing, and are thus perpetuated in the soil, instead of being destroyed by cultivation. Shallow ploughing secures to the crop the nutritive matter of the soil, but at the same time keeps the roots of vegetables so near the surface that they are injuriously affected by both droughts and excessive moisture. We think both theories, therefore, wrong, but capable of modification, so as to make the merits of each available, and to enable us to avoid the evils of each, by the adoption of *substratum ploughing*, as suggested by Gideon Davis, of the District of Columbia. This mode of ploughing is as follows: A small plough, that shall run four inches deep, is followed by a substratum plough, which breaks and loosens the ground six or eight inches deeper, but without turning the soil. By this means the ground is loosened twelve inches deep, and made pervious to water, and to the tap roots of the crop, while, at the same time, the nutritive portions of the soil, the seeds of weeds, &c. are kept near the surface; thus the former is available to the crop, and the latter vegetate, and are within the reach of the cultivator. By the filtering of the water through the surface soil, a portion of the fertilizing salts is carried down, and very soon the whole depth of the ground broken by the substratum plough, becomes charged with nutritive matter. This, we think, is the true theory, and many arguments might be brought forward to illustrate it; among them may be adduced the proposition, that ground thus ploughed will withstand any degree of drought.

As to the question whether the roots of vegetables descend deeply into the ground, that depends upon circumstances. All young seedling trees send down their tap roots to a depth proportioned to that of the loosened and fertile soil. We have often taken up young mulberry trees, whose tap roots had descended two feet, and were as long as the trees were above ground; but when the trees grow on a thin soil that had not been loosened deeply, they were but a few inches in length, and were well supplied with lateral roots. When the ground is loosened deeply, it becomes warmer than when merely stirred superficially, and thus, we think, affords nourishment from a greater depth, and consequently the tap roots of vegetables are induced to descend deeper. It is well known that beets, carrots, parsnips, salsify, clover, lucerne, &c. will send their roots as deep as the warm, well loosened rich soil extends. We have seen parsnips three feet long, and this is not an uncommon thing on deep, warm, loose soils; but on a thin soil—a soil unbroken below a depth of six inches—these same roots would not be over six inches in length.

It seems to us, therefore, that the ground should always be *ploughed shallow*, as a "Pupil" says it should; but that the shallow plough should be followed by a substratum plough, to break and loosen the ground to a good depth—and thus the views of the

editor of the Maine Farmer will be met; and thus the ideas of both parties will be reconciled.

As this is a subject of great importance to farmers every where, we hope our friends, the editor of the Maine Farmer and his correspondent, will excuse this interference in their discussion. We hope to see more on the subject from both their pens.—*Editor American Farmer.*

MR. HOLMES:

Sir,—A few more ideas on ploughing. I consider the subject we are discussing one of vital importance to the agricultural interests; therefore, I am disposed to give your arguments all the weight to which they are entitled. When adverted to by me, I hope I shall treat my instructor with great personal urbanity, and not pervert a single idea that you bring to view. As to the latter of these rules, I apprehend you did not so fully adhere to it, as I presume you meant to do in your remarks, because you say, "I deny that vegetables or their roots run down perpendicularly into the earth, in search of nourishment."—Sir, nothing was farther from my mind, or what I wrote in my first communication on the subject—"True I observed that most vegetables run much farther in a horizontal, than in a perpendicular direction into the earth; and that their roots do not strike into the earth in a perpendicular one. I gave my reasons why it was so, which were, that they might be benefitted by the rays of the sun or heat, dews, showers, air, &c. Nor have I discovered any thing in your remarks on my ideas to counteract them."

All that I objected to against your deep ploughing was, that it appeared that you urged it beyond where vegetables generally (except parsnips, beets, and I add ruta baga, and some other vegetables) went after food or nourishment; but I said to you expressly if you ploughed no deeper than the vegetables you were desirous of planting or sowing descended in a perpendicular direction after nourishment, we were agreed. I named maize as extending its roots much further in a horizontal than a perpendicular direction into the earth, but that it did descend even as far as the roots would be benefitted by the heat, air, dews, &c. no one ever thought of denying. I like your comparison that corn is similar to a tree. The roots of a tree do not strike deep in a downward course into the earth. No, not one ever so old, though you seem to think that corn would if it were not an annual. Here then, we have our argument in a nutshell, as the saying is. I should like to see you dig a deep hole, say six feet deep, and set a young tree out in it, placing the roots four feet under ground, and I say your tree would be ruined, for the very reason, that even trees cannot thrive and grow deep under ground with their roots out of the reach of the influence of heat, moisture, &c. No, sir, the order of nature is against your deep under ground notions. You say if I will travel with you some score of miles, you will show me grass roots three feet deep in an interval bank, which bank (no doubt) was formed by the water from time to time, carrying on various kinds of matter over the roots of the grass in the said bank from which they could not extricate themselves. This no more proves any thing against my position, than it would prove that a man lived that distance under ground because some unfortunate one was found there, buried by accident. I should apprehend this a poor object for such a journey. Forest trees verify my reasoning. Whoever found the roots of such trees very deep in the ground, compared with their horizontal directions? As to your remarks on my views relative to potatoes not doing well if hoed three times with a billock of loam raised around them, I confess I was a little surprised to learn, that the result I named was produced by injury to the roots, in after hoeing them, which do not extend far; and more was I astonished to find that a farmer should call it "theory" for one to assert that potatoes would not prosper deep under ground, even if placed there at planting, and not disturbed afterwards until dug up

in autumn. What is theory? Is it theory whether there is such an animal as man upon earth or not? I presume you will give a negative answer to this question; yet I should as soon have expected an affirmative, as for any one to say that he who asserts that potatoes will not prosper well very deep in the ground is theorizing. Why, sir, the fact has been tried by almost every observing farmer in the world, thousands and ten thousands of times, and there has been but one result, and that is, they will not, if down out of the reach of air, dew, showers, &c.

Now, as to your author, Mr. Powel, I remark, that I respect him as a veteran in agriculture, and yet he may be deceived, not being an oracle. I have before read his piece on deep ploughing, which you was good enough to quote; and then, as now, supposed that he was deceived in some degree as to the cause of the great increase of his crops from year to year, when he ascribes it to deep ploughing. I believe it was more owing to his very heavily manuring from year to year, with so powerful and lasting an ingredient as oyster shell lime. He gives us an account of a very superior crop of mangel wurzel, which I should say might be benefitted by pretty deep ploughing, being a tap root vegetable. And now, sir, I will name a few facts which took place among farmers the last short and cool season. The farmer who manured largely and then ploughed it in deep (as you directed) on sward land, thereby lost his crop of corn, it was so long extending its roots through the sward before it felt the manure, fermenting vegetables, &c. that were buried, that the frost which came early in autumn destroyed it. Not so with mine. Although I could not, owing to the season and kind of land, plant until the 6th of June, yet I had, at least, at the rate of forty bushels to the acre of ripe corn, pumpkins, &c. I took care not to have my manure, and what grass had grown, turned in deep; of course, the roots of the corn were very soon among them, and my corn came forward and got ripe before it was overtaken by the early frost. This is the result of your theory and mine. I now cease to trouble you, or the public any more with my notions about ploughing, as I believe that I have made myself understood in my broken way, after observing that very deep and very shoal ploughing are the two extremes, and that I believe the middle way much the best. Yours, &c. PUPIL.

P. S. I should like to know if you really believe that manure is found deeper in the earth than you send the point of the plough, or in other words, does it go down, or is it exhausted by crops, evaporation, exhalations, &c. An answer to this may settle the question. How you make a soil rich, lower than you can get the point of the plough, for I believe nothing of "the frosts of winter, the rains of Heaven," or any other thing carrying it down further than it is deposited by the cultivator. This, however, is easily tried by taking earth from under a compost heap, and earth not under one, and testing it by a chemical process, and I add, it has been proved in that way, not however consistent with your views, if I rightly understand them.

REMARKS BY THE EDITOR OF THE MAINE FARMER.—We are sorry that our correspondent should think that we perverted any of his ideas, or misquoted him. We have too much respect for one who has so long stood in the front rank in the contest (and it has been no small one) between prejudice on the one hand, and agricultural improvement on the other.

He complains that we perverted his ideas, by stating that he said, that "the roots of vegetables would not run down perpendicularly in search of nourishment." His words are: "your error consists in supposing that you can, by deep ploughing, excite the roots of vegetables to go down in a perpendicular direction to a great extent." And again, he says, "if you mean by that, (deep ploughing,) only so deep as the plants are wont to go in search of nourishment in a perpendicular course, I agree with you. But if you go deeper than that with your plough,

&c. I do not agree with you." Now certainly, he conveys the idea in the above quotations, that vegetables will not strike their roots downward any deeper than ordinary ploughing, for he expressly says, "if you go deeper than that with your plough (that is, deeper than the roots can strike.) I do not agree with you." The same idea, if we mistake not his meaning, is given in the communication above, and he adds that "the roots of a tree do not strike deep in a downward course into the earth; no, not one ever so old." We know not how far he would call "deep" or "to a great extent;" but we have within a week past, set out some trees, the tap root of which was over a foot and a half in length. We have dug up some of the white mulberry trees planted a year ago, in a soil which we purposely spaded very deep, the tap roots of which are over a foot in length. But these he will say are young. We will cite him to an old one. We have been credibly informed by an eye witness, when that what is now called the Factory boarding house, in this village was repaired, it was found that the roots of a Lombardy poplar, which grew near it, had extended downward, plunged under the bottom of the cellar wall, and was busily engaged in undermining or destroying the foundation of the arch upon which the chimney rested. That the roots of plants extended further, much further in a horizontal direction than in a perpendicular, we never denied, but that they would extend down much farther than they do, if farmers by ploughing and manuring would make the soil deeper than they do, we have not a shadow of doubt. In answer to his digging a hole five or six feet deep, and setting out a tree that depth, we say that we never set a tree deeper, or but very little, if at all, deeper than it grew. But we pulverize the earth as deep as we can conveniently, that the roots may have a chance to extend down. The burying of the trunk and thereby killing the tree is no argument against giving the roots fair play.

As touching the potato, and our ideas upon them which surprised our friend so much: he is evidently mistaken in thinking that we doubt the fact, that little ones would be produced by frequent hoeing and hilling. We did not deny, or did not intend to deny the fact. On the contrary we admitted it, and brought forth a different theory from his own to prove it. We did not call the fact theory, but we called his explanation of the fact theory, and do yet.

He asks if it is theory, that there is such an animal as man upon earth or not? We are not disposed to doubt the fact that there is actually such a being as man; but it has been doubted by older and wiser heads than either of ours. Many of the sages of olden time were sadly puzzled upon this subject, and the venerable, pious and worthy Bishop Berkley was in a huge quandary, whether man was a veritable substance, or merely a BUNDLE OF IDEAS. For ourselves, we are willing to take the reasoning of Descartes (if we mistake not) upon this subject,—"I think, therefore, I am"—as proof positive of our personal identity and existence. We grant the fact, that there is *BONA FIDE* such an animal as man; but how he came here—how he stays here—and how he gets away from here is theory, and theory like to be.

Passing from this, to his corn, he says that by shoal ploughing he raised a far better crop than his neighbors who ploughed deeper. Last year was an exception, we hope, to seasons in general. If he raised a better crop last year, on shoal ploughed land, his soil is not so deep thus, as is that of those who ploughed deeper. Besides did he not plant his corn on the margin of a pond? and did not the fog or vapor from the pond check the frost or take it out, and thereby save it, when his neighbor's crops which were further back, were killed? We have for several years, had corn planted in a situation where it was almost surrounded by a river. The fog from this body of water, invariably protects the corn, by extracting the frost gradually, while the crops on a warm sandy plain, a mile further back, are killed.

The idea advanced by us that manure will work down, troubles our correspondent. A friend once observed to us, that clay would dissolve gravel, because, said he, "I once put a large quantity upon my garden, which was a clay soil, and it has now disappeared, nor can I find it by spading the usual depth." On digging deeper, however, we found it. It was first buried by the usual spading. The frosts, rains &c. had buried it deeper than the point of the spade had usually been put. It may be objected to this, that manure is not so solid and heavy as sand and gravel. True, but a part of it will become dissolved of course by the rains, and by this means sink, and the dried fibre, if buried at the bottom of the furrow, must and will stand a chance to work down by the alternate rising and falling of the earth by frost.

The whole difference of opinion on the subject of ploughing must be settled by an answer to this simple question: Which is best, a shallow or a deep soil?

(From the Fredericksburg (Va.) Herald.)

ON RAISING POTATOES.

MR. HARROW:

In passing through our streets the other day, I could but observe the Irish potatoes, placed at the door of almost every house of business; on asking the price, I was told that one hundred bushels could be had at one shilling per bushel, and in lots of twenty bushels, at twenty cents per bushel. Now, sir, as we look for you to correct whatever goes amiss in domestic as well as political economy, would it not be kindly received by the readers of your paper, especially farmers, to give them a hint at the policy pursued by them, in the general neglect of this most valuable root. Its cultivation in the first place, is perhaps, of all others, the least difficult, as well as requiring the least labor—none possessing more nutriment, adapted to the constitution of both man and beast. It has its place upon the President's table as well as the cottager's, and is no less the choice vegetable of the delicate and blooming lady than the rustic ploughman.—The season for planting this invaluable article is near at hand, from the 1st June to the 15th or 20th July, for fall use, (in light and quick soils,) the time of laying by the corn is the time to plant them, in the last middle furrow, and the dirt gently thrown back upon them, they need no further cultivation, and have often yielded ten, fifteen and twenty bushels for one of seed. Again, the stubble of wheat is a fine preparation, a slight furrow and the potato placed in, and the dirt thrown back on each side, will, with the September rains, produce an abundant crop, without further cultivation, when the soil is light and active, and is found to be a great improver of the soil, yielding two crops in the season. Now, the uses of this famous root, beside that for the table, and as a substitute for bread, hogs, sheep, oxen, milch cows are very fond of them, and when boiled with a little salt and bran, nothing is more improving to their health and general good condition. Hogs, especially when in pens, fatten and grow more rapidly than with corn, always less liable to fever and costiveness. Would farmers pay a little attention to this article, they might largely increase the sale of their corn crop, which is often wasted without the improvement of their pork, except to harden the flesh. A simple calculation will easily show how it is that the eastern farmers make their little farms (not in all as large as one of our ordinary size-fields) produce so much. They calculate each acre in corn will produce 50 bushels—the same planted with potatoes, in laying by the corn, will produce from 250 to 250 bushels, according to the season. The first is worth, generally, 60 cents per bushel, is \$30 00 The latter, say 250 bushels, at 25 cents per bushel, though often more, is 62 50

This received from a single acre, \$92 50
In the same proportion, 20 acres will yield the sur-

prising amount, at ordinary prices, of \$1950. The lots in wheat about the same degree. Notwithstanding these almost certain results from such a system, we find our small farmers particularly, with, perhaps, a single horse to draw the plough, delve from year to year, at corn alone, and often before the 1st March have to look out to some kind neighbor to loan them a little corn for bread, to get on until fruit season. Not to say any thing about the smoke house, which, except in grass season, never has had introduced into it a single sty hog, a fat beef, mutton or pig. Why this? Ask the yankee. He will say, because you neglect the simple and easy culture of Irish potatoes.

Suppose, again, you take \$10 and purchase 50 bushels at the market price and plant them on the 1st July, or on the 15th, if you please, either in wheat stubble, or corn, ground—in the short period of ninety days you will gather your crop—at a moderate calculation you will get ten bushels for one of seed, making 500 bushels—which will sell for seldom less than 30 or 35 cents—take the least price and you have \$150 for the ten advanced for 90 days, and so in proportion, by the few days' labor of your least effective hands.

Who is it that has felt the ravages of the Hessian fly, and with hopes all blasted with regard to meeting promptly and at Christmas bonds for hires, &c. let him be up and doing while the season invites, and seed can be had, cultivate potatoes; who the last year had the last existence of his smoke house drawn out with sighs and groans and a useless dairy—let him plant potatoes; who labors to maintain his punctuality and is desirous to behold his helpmate cheerful, and his children happy—let him plant potatoes.

(From the Virginia Herald.)

A TIMELY HINT—CULTURE OF POTATOES.

Who that has a field of forty acres in corn or in wheat, with labor in proportion, and feels ambitious to vie with his neighbor who has sixty; let him cultivate potatoes—Then make his calculation by the good old rule of three, viz:

If 1 acre give \$92	what will 20 give?	Ans. \$1840.00
If 20 " " 1840	" " 40 " "	3680 00
If 40 " " 3680	" " 60 " "	4906.67

\$10426.67

Now, sir, contrast this with the short-sighted policy of corn and wheat alone; take the first, as it generally yields most, and apply the same good old rule, viz:

If one acre give 50 bushels at 60 cents	what will 20 give?	Ans. \$600.00
If 20 acres give 5600, what will 40 give?	" " 40 " "	\$1200.00
If 40 acres " \$1200, what will 60 give?	" " 60 " "	\$1800.00

\$3600.00

Total loss by neglecting to cultivate potatoes, \$6826.67

You will observe this calculation is founded upon the largest scale in favor of the corn, as to product as well as price, say 60 cents per bushel, and the smallest against potatoes, yet 200 per cent. is gained by them. I might here give a hint at the present state of the meat market, the scarcity, poor quality and high prices, &c. and advert to the amount annually sent out of the state for pork and potatoes, and show the amount of tribute we pay annually, by neglecting the cultivation of Irish potatoes. Under these fair prospects can it be possible that farmers will hold on upon the old impoverishing policy, and close their eyes and ears against these calculations, till the season glides by, and suffer the fine lots now in market to spoil upon the merchant's hands, and say next fall, the fly, rust, grub worm, &c. &c., ruined their crop, and they can't pay their accounts till next year? No, no—advise them to look to it, and plant potatoes, or they will be left without excuse.

A SUBSCRIBER.

(From the Maine Farmer.)

RAISING PEAS FOR SWINE, &c.

MR. HOLMES: *Winthrop, April 17, 1833.*

In the year 1805, I purchased the farm where I now live, on which there was not more than four and a half tons of hay cut the first year I improved it, although there were many acres mowed over. I ploughed the spear grass sward, and put on one and a half bushels of plaster per acre, and sowed to peas, and peas and oats. I had the Newbury white breed of hogs. I turned them into the peas when in the milk, or rather a little before, when they were so tender that the hogs would eat pods and all.

I kept them in these, by fencing a small enclosure, until all the peas were eaten; then moved the fence to a fresh portion. Two boards in height were sufficient for that breed. By two or three sowings I was enabled to feed them in this way during August and September.

I then mowed my peas and oats, and while they were becoming sufficiently dry to thrash, I picked the pods from those stakes which had the most upon them, and gave them to my hogs in the yard, and when Indian corn was harvested, I gave them the small corn. Immediately after harvesting Indian corn, I threshed my peas and oats, and had them ground, set a half hoghead on the south side of the house and mixed up a quantity of the meal for the hogs, adding steamed or boiled potatoes, taking care not to let the mixture sour, but to get into a raised or slightly fermenting state. The course adopted by me of turning the hogs into the peas, often occasioned some mistakes, for many a time would some kind good hearted person call and tell me very earnestly, that *the hogs were in the peas*.

I relied upon the sale of pork to pay a hired hand, and did it for a number of years.

I afterwards came into the possession of another farm, from which I brought the hay and spent it on the one where I lived. I was thus enabled to manure highly, my peas ran to vines, and I gave up the raising of them for other crops. I am now about ploughing a back field and introducing the same mode of culture, it being too much labor to cart the manure to it. I was probably the first who introduced this kind of culture in the county, and I suffered from ignorance, as to the quantity of seed necessary to be used. I have now eight bushels of peas to sow this year, and shall sow them in the following manner; of those that are intended to be eaten off, I shall sow one and a half bushel of peas and a half bushel of oats, (the oats well incorporated or mixed with the peas to hold them up when growing.)

If intended to be cut as peas and oats, I shall sow five pecks of peas and a bushel of oats; more peas ought to be sowed than oats, for the oats will gain on the peas. I find that the peas and oats ought to be raised together for a number of years that they might ripen at the same time. I consider the pea and oat crop as the most convenient and valuable crop that I can raise; as food for hogs and horses it surely is the first. With respect, yours, E. Wood.

(From the Kennebec Farmer.)

CULTURE OF THE RUTA BAGA.

MR. HOLMES: *Monmouth, Feb. 4, 1833.*

Josiah Richardson, Esq. of this town, has raised the last season, on a small piece of ground at the rate of eight hundred bushels of ruta baga to the acre, (after being closely cut,) but as the ground on which they were raised was not sufficiently large to obtain a premium, he did not present a claim for that purpose, to the Agricultural Society. The same person a few years since raised from a small piece of adjoining land, at the rate of two thousand one hundred and odd bushels of carrots to the acre. The ruta baga were raised on land turned over in May which had never before been ploughed. They were sowed the 22d day of June, and when harvested, some measured two feet five and a half inches in circumference.

A FRIEND TO FARMERS.

HORTICULTURE.

(From the London Gardener's Magazine.)

ON THE MEANS OF PROLONGING THE DURATION OF VALUABLE VARIETIES OF FRUITS. By THOMAS A. KNIGHT, Esq. F. R. S. President. Read May 3, 1831.

Mr. Knight believes that all the constitutional properties of every variety of fruit are contemporaneously inherent in all the plants which can be made from the buds of that variety, if taken as they usually are from the branches, be the mode of multiplying the buds of these branches into plants what it may. No trees of any variety can be made to produce blossoms or fruit, till the original tree of that variety has attained its age of puberty; and under our ordinary modes of propagation by grafts and buds, all [the individual plants of any given variety, as we understand it] become subject, within no very distant period, to the debilities and diseases of old age. It is therefore desirable that the planter should know at what periods of their existence varieties of fruits are most productive and eligible; and by what means (if any exist) the deterioration of valuable varieties may be prevented or retarded." Mr. Knight has been accustomed to consider "that each variety possessed its greatest value in its middle age," but now believes, "that in vegetable as in animal life, the most prolific period is that which immediately succeeds the age of puberty." Out of a good many experiments which led Mr. Knight to this conclusion were these:—From seedling pear trees twenty years of age, and which had borne their first fruit in the preceding autumn, he, in July, 1828, took from the extremity of their leading branches buds, and inserted them into seedling pear stocks, then only four months old. Many of these budded plants, although not transplanted, nor subjected to any peculiar mode of treatment, produced blossoms abundantly vigorous in the spring of 1831, and consequently at but three years from the date of their springing from the ground. Mr. Knight remarks:—"I never previously saw, and I do not think that any other person has seen, in this climate, fruit produced by pear trees at so early an age. I had previously made the same experiment with apple trees, with the same results." Mr. Knight laid some branches of a plum tree, which had not attained the age of puberty, which (as he expected) freely emitted roots; but he found, contrary to his expectation, that the young shoots which these layers had produced afforded, in the following spring, much blossom. The variety of plum experimented on, Mr. Knight believes to be one exceedingly productive of blossoms; "but," he adds, "I doubt much if such blossoms would have appeared, if the variety had been a century old." Thus, while Mr. Knight hence infers that grafts or seeds taken from the bearing branches of very young seedling trees afford trees capable of bearing freely at a very early age, and, in

consequence of their youthfulness, likely to continue to grow with health and vigor; yet he readily admits that this information will not subserve the object of prolonging the duration of existing varieties of fruits, if every part of seedling trees is in the same degree affected by age. This, however, Mr. Knight states, is not the case; for "the decay of the powers of life in the roots of seedling trees is exceedingly slow, comparatively with [the decay of the powers of life in] the bearing branches. Scions [shoots] obtained from the roots of pear trees of two hundred years old afford grafts which grow with great vigor, and which, in many cases, are covered with thorns, like young seedling stocks; whilst other grafts, taken at the same time from the extremities of the branches of such trees, present a totally different character, and a very slow and unhealthy growth. I do not, however, conceive that any scion [shoots] which thus springs from the root of an old tree possesses all the powers of a young seedling tree; but it certainly possesses no inconsiderable portion of such powers; and I have proved such scions to be capable of affording healthy trees of a considerable size.

"If grafts or buds were taken from such scions [shoots] on their first emission, [from the roots,] much time would elapse before any blossom would be produced; but, if buds were not taken from such scions [shoots] till the branches attained the age of puberty, no loss of time whatever would subsequently occur.

"The branches of the plum tree, in the experiment above mentioned, emitted roots just at the period when they had attained the age of puberty; and I do not doubt but that scions [shoots] from the roots of these will spring from the soil, in full possession of all the powers attached to the branches from which they derived their existence. My own experience leads me to think that trees of the pear, the apple, and the plum may be better raised by layers and cuttings of the roots, than by the methods usually practised, and at a less expense."

Mr. Knight remarks, in conclusion, that the permanent preservation of valuable and new varieties of fruits, of which the society's garden contains many, in their pristine and present state of health and vigor, appears to be an object of great importance; as does the retardation of the decay of many varieties, "such as the Cornish gilliflower apple, which, in my estimation, is and always was without a rival in the climate of England."

(From the Genesee Farmer.)

NEW AND DESIRABLE FLOWER GARDEN PLANTS.

"The following plants we would particularly recommend as deserving a place in every good flower garden, viz:—1, *Salvia cardinalis*; 2, *Fuchsia melandris*; 3, *Feenimocarpus scaber*; 4, *Lophospermum scandens*, *Salpiglossus*, all the species; the newly introduced [species of] *Penstemon*, *Lupinus*; 5, *Calceolaria*, *Potentilla*, *Gemm coccineum*, *Gemm Quillyon*; 12, *Mammadia Barcliana*, *Mimulus moschatus*, &c.

"Of these, the third, fourth, and twelfth, are climbing plants, and suited for training against walls, pales, or rustic supports. They should be propagated by cuttings in autumn, and kept in pots in the green house during winter, and planted out in April or May. The first, second, and eighth, average two feet in height, and require the same protection. The remainder are sufficiently hardy to stand in the open borders. Of the genus *Lupinus*, several are annuals, and should be raised from seed in the spring. *Salpiglossus picta*, *atropurpurea*, *stanina*, and *Barcliana*, are hardy biennials or perennials and may be propagated from seeds which should be sown in April and May."—*Mintosh's (British) Flora and Pomona*.

REMARKS BY A CORRESPONDENT.—The following particulars respecting some of those plants, are selected from the same work. It has been gratifying to observe that seeds of many of the kinds recommended, are now on sale for the first time in this country, by

PROCURING TWO CROPS OF THE ASH-LEAVED KIDNEY POTATO, IN ONE YEAR OFF THE SAME GROUND.—In each of the last two years I have grown two crops of the ash leaved kidney potato on the same ground, and each of the crops has been a good one. I proceed thus:—In taking up the first crop, I bury the tops or herbage in the trench, by turning the earth between the rows upon them, and this done, the ground is ready to be planted again. My first crop this year was planted on the 30th of March, and my second on the 12th of July; the second has been as good as the first, and the potatoes are perfectly ripened; the joint produce of the two crops has been fully at the rate of nine hundred and sixty bushels an acre. I took some of the potatoes of the second crop, of nearly the full size, to market on 15th September.—*Loudon's Mag.*

ALEXANDER GORDON, at the Rochester Nursery, New York. I hope our florists will take advantage of this opportunity to embellish their gardens.

Calceolaria corymbosa has yellow flowers, delicately striped near the orifice with red, and dotted with the same bright color in other parts. It is a native of Chili; grows from one to two feet high; flowers from April to August; and thrives in peat and loam. It is a biennial, and may be propagated by seeds or by dividing the roots.

The temperate regions of Chili and Peru are said to abound in many splendid species of this genus.—The prevailing color is yellow. They are all readily increased either by seeds or cuttings; and most of them are well calculated for planting out in the borders of the flower garden during the summer months. As green house plants, they are all peculiarly interesting, and cannot fail of obtaining admission into every collection where there is the least pretension to a taste for plants.

Ecrenocarpus scabra, also called *Calampelis scabra*, is a native of South America. The flowers are somewhat tubular, finely shaded with red and yellow, and grow in racemes. The plant is a half shrubby perennial, growing from six to twenty feet high, and flowering from July to October.

It is a rapid growing plant, which in its native country is found running over the hedges and bushes, and flowering nearly the whole year. It is propagated by seeds which are produced in tolerable abundance, but do not vegetate sometimes till the second year after sowing.

Goum coriucum is supposed to be a native of Chili. It grows from one to two feet high, with scarlet flowers in June and July. The native country of this extremely beautiful plant, is not correctly known. It is of the easiest culture, seeding abundantly and increasing at the roots. Perennial.

Verbena melindris is a native of Chili and Buenos Ayres, grows six or eight inches high, and flowers from June to September. It is perennial; and propagated from cuttings. The flowers bright scarlet, arranged into a corymbous spike.

This, of all the genus is the most splendid, and the most deserving the attention of the flower gardener. The facility with which it is increased by cuttings; and naturally when planted out, by rooting from the prostrate stems, has already rendered it common in all the best gardens in the vicinity of London. For the decoration of the green-house, conservatory, and drawing room, few dwarf growing plants can exceed it; and although it requires the protection of a frame during winter, it is among the greatest acquisitions that the flower garden has recently received.

Lophospermum scandens, called also *Besleria scandens* is from Mexico. It is perennial; grows from five to twenty feet high, with flowers varying from purple to a rose color, which appear from July to October. It is propagated by seeds or young cuttings.

As a green-house, or conservatory climber, this plant has few equals; and to the list of flower garden climbers, it also adds a valuable addition.

Maurandia barclata is also from Mexico, grows from seeds and cuttings, four to ten feet high, and flowers from May to December. Corolla nearly three inches long, deep purple, tubular-bell shape. For green-house and conservatory climbers, they are admirably adapted, being rapid in their growth, and continuing long in flower. During the summer months they may be planted out in beds in the flower garden, or trained to trellises with advantage. It is perennial.

Lupinus. So late as 1826, we find only fifteen species of this genus enumerated in Sweet's Hortus Britannicus, as being in cultivation; but in the course of the following year, an additional fourteen new and valuable species, was made to this list by the indefatigable exertions of Mr. David Douglas, a botanical collector, employed by the Horticultural Society of London, in exploring the rich vegetation of the almost un-

trodden territories in the vicinity of the river Columbia, in the northwestern districts of North America.

Professor Nuttall says in his introduction, "the trees and shrubs of cold climates retain the necessary moisture of their vitality at temperatures when all other liquids freeze." p. 223.

If by this moisture is meant the sap, the passage is erroneous. There is not a winter of the Genesee country in which the sap of the maple, the beech, and the basswood is not frozen very hard; and the labor of cutting wood at such a time is very much increased, as every farmer who cuts his own fire-wood well knows. Nor can it be said that it is different with evergreens: the hemlock (*Pinus canadensis*) for instance, freezes as hard as the basswood.

A PRACTICAL GARDENER.

(From the New England Farmer.)

SEEDS FROM COM. PORTER.

Proceedings of the Massachusetts Horticultural Society, at a meeting held in the Hall of the Institution, on Saturday, the 18th of May, 1833.

H. A. S. Dearborn, the President of the Society, made the following Report:—

It will be recollected, that during the last season, a communication was received from DAVID PORTER, Esq. Charge D'Affairs of the United States, at the Ottoman Porte, in which he kindly proffered his services, in procuring and transmitting such seeds and plants as the society might be desirous of possessing. Having so favorable an opportunity to increase the varieties of our fruit, timber, and ornamental trees, and culinary vegetables, I wrote him last autumn, that it would be considered a great favor, if he could obtain and forward seeds of the Gul Ibrischim,—samples of the grapevines, cherries and other fruits of the Crimea,—seeds of such forest trees as were considered valuable for economical purposes, and of such other plants as would flourish in our climate.—Within a few days the following letter has been received, with the seeds therein named.

Pera, Jan. 3, 1833.

SIR,—I have received your favor of the 25th Sept. 1832, accompanied by a diploma, with which the society over which you preside, has honored me as corresponding member. Also a number of the New England Farmer, noticing my communication respecting the beautiful Gual Aghadj.

As the name of H. E. the Baron Ottenfels is mentioned in that communication, I took the liberty of sending it to him, and he did me the honor to call on me the next day, bringing with him a quantity of the seeds of the tree to which the communication alludes, as growing in his garden; he had collected them for the purpose of taking with him to Vienna, for which place he takes his departure from here in a few days.

These seeds, which are fresh from the tree, he desired me to present in his name to the society. They are not exactly the kind which I sent to Mr. Skinner, but a variety of the same family, and I am in hopes may prove still more beautiful. The Baron calls the tree the Gul (Gual) Ibrischim, the seeds are larger and blacker than those of the Gual Aghadj. The pod is nearly double the size. Gual, as I mentioned in my former communication, is the Turkish for rose. Ibrischim as nearly as I can ascertain means silk tassel. The silk tassel rose is certainly a most appropriate name for it. Yet I should be sorry that it should lose the name which it bears in Turkish.

A few of the seeds I shall put up in this letter, the remainder I shall put up in a clean tin box, and let it take its chance with the hope of reaching you.

The north will be able to exchange with the south; and it is worth making the exchange, for there cannot be a doubt that they are varieties. If one of each comes to maturity, I shall feel myself well rewarded in the satisfaction of having introduced so beautiful an object into our gardens. It is a hardy plant, it flourishes here in forty-one degrees, but it is not so

cold as in the same latitude in America, yet I have no doubt it will thrive in Massachusetts.

I have endeavored in vain to find the plana you mention, or to get some intelligence respecting it.—Mr. Eckford, could give me no information about it, nor could Mr. Rhoades, his farmer, who is something of a botanist. Both, however, assured me that they had the live oak here equal to that in the United States, and they have shown me several fine trees of it growing. The Turks are ignorant of the treasure they possess. Their timber for ship building is, take it altogether, the finest in the world. I have never seen such fine lots of wood, for the frames of ships, as I have seen delivered from vessels at the Navy Yard, not cut exactly to mold, but nearly so. It is brought chiefly from the Black Sea. Immense rafts of pines pars are annually brought down from thence to Constantinople.

A long spell of sickness, the prevalence of the plague, and various other causes, have prevented my being as active as I should have otherwise been, but the prospect of a return of health encourages the hope, that next spring and summer, I shall be able to accomplish all the wishes of the society as expressed in your letter. With great respect, your most obedient servant,

DAVID PORTER.

To the President of the Mass. Hor. Soc. Boston.

(From the Genesee Farmer.)

QUINCE TREES.

MESSES. EDITORS:

In the Genesee Farmer, I noticed an article on the subject of injury, and final destruction, of quince trees by worms. For the benefit of your correspondent and all others concerned in cultivating the quince, I will give the result of actual experiment.

In the spring of 1823, I procured some trees of the orange or apple quince, and set them in rather moist, rich soil. They all lived, and as they were of a good size, soon commenced bearing. I saw an article in some work, recommending coal dust, or the dirt from the bottom of a coal pit, to be put around quince tree. I tried the experiment, and it succeeded equal to my most sanguine expectations. While my trees were doing well, a neighbor suggested the plan of manuring trees, and (like the man who was well, but took medicine to be better) I manured my trees, but not long after discovered worms or grubs in them, near the top of the ground, and in cutting them out, injured the trees so much that they all died but one, and that is a poor sickly one.

The next year, 1824, I set other quinces of the same sort, and have kept the coal dust around them altogether, and the result is, the trees are uncommonly thrifty, good bearers, produce very large and fair fruit, and I have seen no appearance of the grub.—My plan is to renew the dirt, say once in two years, first scraping away the old dirt, and putting on a bushel or two of fresh. Yours, &c.

C. OF STARKEY.

RURAL ECONOMY.

(From the Southern Agriculturist.)

ON THE MAKING OF RASPBERRY AND STRAWBERRY CORDIALS, CIDER AND WINE; a' so, observations on the growing of Sugar Cane, in the lower part of South Carolina.

St. Matthew's Parish, November 1, 1832.

One gallon of raspberries or strawberries when properly mashed, squeezed, and the juice mixed with the requisite quantity of water, sugar and brandy, will make one and a half gallons of rich beautiful cordial, having all the good qualities of madena wine. There is no loss in adding sugar to the fresh juice, as the quantity increased thereby, is of more value than the sweetening. Two years since last July, I made a barrel of permanent cordial, like cider, without brandy. I took the pure juice of the ripest apples, sweet-

ening it at the rate of half a pound of Muscovado sugar to the gallon, I took then an empty cask, and after fumigating it well with the smoke of brimstone, I poured into it through a strainer about three gallons of the juice, then fumigated it again with the brimstone smoke, what the cask could contain, closed the bung, rolled the barrel backwards and forwards for the purpose of impregnating the enclosed liquid with sulphurous fume; repeated the process of pouring in, tumbling and rolling, till the cask was filled, then bunged it up tight, placing it where it would be kept steady and free from perturbation, not meddling with it till Christmas, when I broached it, and better cider I never tasted. I never tried the experiment with any liquid but the juice of the apple: I expect the same process would succeed similarly with the juice of the grape or that of any other kind of fruit.

To convert the simple vinous juice of any fruit into an exhilarating salubrious cordial, without the admixture of other ingredients, is a great desideratum. This cannot be readily done, but by confining it in receptacles impervious to the atmosphere. The ancient Phenicians, it was thought, made the best wine in the world; and their method was to fashion a green beef hide, in the most suitable manner for making a portable receptacle—closed it with seams impervious to the air, filled it with the *must*, then put it where it could be kept cool and unmolesied. This, when complete, was called "a bottle of wine." The elastic quality of the green hide, renders it a useful substance for containing new wine, as it resists the impetus of its fermentation, which sometimes bursts glass, and forces the whizzing fume and liquid through the seams of the tightest casks. This, in my humble opinion, is the only method, by which good wine can be made in a warm climate, exclusive of artificial agency. And even this method was not always exempt from said agency, for the *must*, intended for the first rate quality of wine, was boiled, mixed with honey and spices, bottled in the largest kind of hides, rested on its lees till the commencement of the cold weather of the second winter; when it was carefully racked off into smaller bottles made mostly of the skins of sheep and goats. I expect this was the manner of making the celebrated nectar.

If fruit cider and wine are so estimable in a pecuniary point of view, they are more so as promoters of health, strength, and cheerfulness; as remedies for sickness and a preventative for many disorders. In the sickly districts of France and Germany, as I am credibly informed, the fever disappears at the approach of the vintage, although it is naturally the sickliest season of the year, and the failure of fruit there is considered as a two-fold public calamity: for besides the loss of the staple commodity, sickness, if not pestilence, is pretty sure to follow. But why cross the Atlantic for instances when there is a sufficiency at home? The cider districts of the maritime parts of New Jersey, Delaware, Maryland and Virginia, are naturally, perhaps, as sickly as any part of South Carolina; but fevers there abate at the approach of the cider season, and diminish in proportion as it advances until they entirely disappear. Many of the farmers in those states dread a failure of fruit as they would the failure of harvest; indeed, the fruit of many of their farms is their most valuable production, witness that of Mr. Jones, of New Jersey, (mentioned in one of your journals,) which produces annually about seven thousand dollars worth of peaches alone, setting aside the valuable produce of his other fine orchards of apples.

The all-wise Author of nature in order to overbalance evil with good, has bountifully granted some benefit which commonly more than compensates for the natural disadvantages peculiar to any state or country. Thus in febrile regions the soil and the climate are capable of producing the cure and preventive. I know of nothing that would contribute more to the comfort and advantage of the citizens of this state, than the rearing of fruit, the cultivation of the

sugar cane, and the valuable grasses, (such as the gama grass and the wild oats;) the encouraging the introduction of valuable exotics, and the promoting the cultivation of valuable plants. We already have to promote the rearing of stock of every kind, and to prepare for the total abandonment of the culture of cotton, except for domestic use. The quantity of fruit trees in this part of the state has greatly diminished since the commencement of the present century, owing to the emigration of the small planters whose plantations were mostly sold to great ones, who destroyed the orchards for the purpose of raising cotton on the ground where they stood, and to prevent the fruit being pilfered and carried off by the neighboring negroes, for in some places it is an aggravating misfortune for a person to have an orchard. I have had nearly half of my apples stolen and carried off in the night. Was every planter in the state obliged to plant an orchard of apple and peach trees, of the early and late kinds in proportion to the number of his slaves, say five trees of each, for every one of his negroes, it would, I think, be the happiest obligation that South Carolina was ever laid under.

When an agricultural article becomes a first rate staple, it seems difficult to abandon it, even when its culture proves to be entirely disadvantageous. The planters in the upper part of this state were a long time before they could be prevailed upon to substitute the rearing of cotton for that of tobacco, although the latter had become something worse than unprofitable, and they seem now to be similarly disposed, not in the upper parts only, but all over the state.

And the cotton planters appear to be determined to persevere in its culture, although they should get nothing but their labor for their pains. Since the invention of the labor-saving machines for ginning and manufacturing, there are few or no productions of agriculture that are and have been more estimable on account of their utility than cotton, and there are few or none that have ever been known to have outgrown their demand so rapidly, and so completely, as what cotton has done. It seems as if all mankind were concerned and combined in promoting its production.—Sixteen years ago there was no cotton exported from Virginia, Mississippi, Alabama nor Florida, and sixteen years ago, there was no cotton exported from Brazil, nor any of the South American states, nor from the East Indies, nor from Egypt; and these now are all great cotton growing and cotton exporting countries. Is it not then much more a matter of astonishment that cotton gets the price it does, than that it should be reduced to what it is?

I have reason to believe that the climate of the lower half of South Carolina is more favorable to the growth of sugar cane than that of Louisiana. Being situated southwest of the Alleghany mountains, which wafts or wards off the north wind, and as it were, guards vegetation from the fatal effects of the chilling northern blast, and of the early killing frosts of autumn till the snow covers the mountains, which seldom happens till after Christmas.

On the contrary, Louisiana is much exposed; although located several degrees south of the parallel of Charleston, yet her locality renders her much more northern than her latitude warrants. Situated near the mouth of one of the longest rivers in the world, which with its grand contributor, the Missouri, opens avenues to the frozen regions, from whence the northern winds having no obstruction to retard or bias them, descend upon her with unabating celerity, and often bring premature winter and extremely cold weather when least expected. The proximity of the Gulf of Mexico also facilitates the operations of old Boreas by its warm temperature and consequent rarefaction of the encompassing air, acts as a draft to the colder northern atmosphere, and brings down the breath of the frigid zone in a very short time.

I have read in a newspaper, (though in what paper I cannot now recollect,) that a captain of a vessel and his crew were frozen to death on Lake Ponchartrain,

on the night of January 19th, 1817. From a circumstance that took place in my family, I remember the day perfectly well, it was on a Saturday, and a very cold day, but not so cold as many a one we have had since. I frequently see accounts in the newspapers of the crops being injured in Louisiana, by early autumnal frosts. In the year 1830, the damage was immense, supposed to be more than half of the sugar crop, occasioned by unseasonable frosts that happened in October and November. In that year, with us, or in this neighborhood, there was no frost till the first of December, and that so light as not to injure vegetation.

Within a few years, in different parts of this district, I have seen several small patches of sugar cane, they all grew, thrived and matured beyond expectation; and I never knew a sugar cane to be injured by frost, previous to its being cut. Those that have been cut and put away for seed, have been injured by the cold; but the cause of that was ignorance of the right way of taking care of them. A SMALL PLANTER.

(From the New York Farmer.)

ABSORBENT PROPERTIES OF POTASH.—PLOUGHING IN DRY WEATHER.

MR. FLEET: *Middlesex, Feb. 15, 1833.*
I am not quite done with the subject of ploughing and hoeing in dry weather. From the remarks made on potash, vol. 5, page 321, of the Farmer, two things may be inferred; first that it takes fourteen pounds of water to dissolve one pound of potash, and consequently that it will take seven thousand pounds of water to dissolve an ordinary barrel of five hundred pounds of potash. This is the least quantity of water in which a barrel of potash can be dissolved. Many years ago, a boat was loaded on Cayuga lake with fifty-six barrels of potash. On the Oneida lake they met with a squall, were driven ashore and sunk. The potash barrels being leaky, and remaining in the water from half an hour to an hour and a half, took in as much water as they would contain. This water swelled the barrels so that they became tight. In this situation the captain procured two potash kettles with tubs, wood and other articles, with a view of dissolving, boiling down, and melting the whole of the fifty-six barrels. The circumstances being mentioned to me, I observed that the boiling would be unnecessary, as the potash in the barrels would soon absorb all the water, which could not exceed ten gallons to the barrel, and the potash would pass inspection without melting over, and consequently save the expense of boiling, melting, &c. The ten gallons of water could not weigh over ninety pounds, where as it would take seven thousand pounds to dissolve it.—The experiment was tried and the potash was sent to market for inspection, and was sold as *first sort*, so that the expense of boiling away three hundred and ninety-two thousand pounds of water, and all the other expenses of such an undertaking, were saved.

From this it will appear that it is not altogether useless to know how many pounds of water will dissolve one pound of potash. The atmosphere holds much moisture, or water dissolved in caloric, as is evident from the circumstance mentioned p. 321, vol. 5, of the Farmer. Another experiment will serve to demonstrate the same fact. Take a tumbler, fill it with cold water, set it on a table in warm weather, and in a few minutes the tumbler will be covered with a dew. This experiment is easily tried, and the rationale I take to be as follows:—Caloric always seeks an equilibrium; it passes through the tumbler, and combines with the cold water until the water is brought to the temperature of the air. The water held in solution is deposited on the outside of the tumbler, and this circumstance will occur in the driest weather. It would seem then demonstrated, that the atmosphere holds in solution much moisture, and though invisible to us it is still large in quantity. Now let us apply this doctrine to ploughing and hoe-

ing in dry weather. Where land is left unploughed, unhoed, and covered with grass and weeds, the crops are seen to dwindle; stir the ground, and they speedily revive. By ploughing and hoeing, the grass and weeds are destroyed, and the earth becomes a powerful absorbent, drawing the moisture of the atmosphere into the neighborhood of the plants. The capillary vessels of plants seize this moisture; it reaches the roots and sustains them in a flourishing condition, even in the driest weather. The moment this moisture is condensed, it can no longer enter the capillary vessels of plants. This probably carries with it much food and is every way necessary to the well being of the plants: so I think, and remain,

Yours, &c.

R. M. W.

(From the Maine Farmer.)

A MACHINE TO TURN HAY, GRASS AND POTATOES TO CASH.

MR. HOLMES:

May 1, 1833.

I fell in company, a few days since, with that distinguished and industrious farmer, Ariel Tinkham, of Anson, in the county of Somerset. He told me that he had discovered the above machine to turn the above articles into cash, and that he was not obliged to trust them to poor people and not get his pay.

The machine is this: he took a pair of steer calves, well mated, of the breed introduced into that country by Daniel Shaw, Esq. of Industry; suckled them, and after weaning kept them well until they were three years old, and from his description, I did not think there was any thing peculiar in their keeping until that time. The summer after they were three, he gave them the best feed, and we are to suppose it was good, as he is a good farmer, and has SEVEN HUNDRED acres of land in his farm (as I have been informed.)

The winter after they were three years old, he put them upon the best of hay, and gave them sixty bushels of boiled potatoes. Next spring he sold them for ONE HUNDRED AND FORTY DOLLARS, to a man who drove them to the Canada market.

They were the best of beef, and had never had a yoke upon them. I understood him that he was preparing to enter upon the business on a more extensive scale, and had no doubt as to the profit. The Canada market is not easily supplied, and I see no good reason why every farmer may not do the same, as there is no patent taken out, nor is the patent or copy-right secured. We calculated the cost of the steers, keep, &c. as hay sells there, setting the price of potatoes at twenty-five cents the bushel, and found that they cost him eighty-three dollars. If we can do so with our potatoes, we need not trouble ourselves about making potato starch or sugar to get the cash for them. I believe the potatoes might be cooked much easier by steam. It seems necessary that they should be of a large breed, and he said that he would have them as well shaped and mated as if he intended to work them. They were so managed as to arrive to maturity while young. Now is there not a saving in that? It is all practicable, for it has been done, and can be done again. The clear profit on these steers, if eighty-three dollars were the cost, is fifty-seven dollars.

E. J.

REMARKS BY THE EDITOR.—We remember having seen and examined Mr. T's steers, and confess that we never saw handsomer cattle. It must be taken into consideration, however, by all who think of engaging in using the above "machine," that Mr. Tinkham has some of the best grazing land in the state.

NEW CEMENT.—The late conquest of Algiers by the French has made known a cement used in the public works of that city. It is composed of two parts of ashes, three of clay and one of sand. This composition, called by the Moors, *Fabbi*, being again mixed with oil, resists the inclemencies of the weather better than marble itself.—*Beija Flor*.

MISCELLANEOUS.

EDUCATION OF FARMERS.

The following are extracts from a pamphlet entitled, "The Cause of Farmers, and the University in Tennessee," by PHILIP LINDSEY, D. D.

Democratic and republican as we are, our citizens are strangely partial to great names. Esquire, Honorable, Excellency, Major, Colonel, General, Doctor, are as much coveted and as eagerly sought after in this country, as are titles of nobility in Europe. And foreign titled gentry, when they condescend to visit us, are regarded and treated as a superior race. The wealthiest and proudest man in the United States would feel himself and family wondrously honored and *renewed*, could he be so fortunate as to marry his daughter to an English earl or even baronet! This spirit, so utterly at variance with our constitution and avowed political doctrines, is sufficiently contemptible to be left, without serious comment, to the ridicule which it merits, were it not for some of its deleterious practical effects on society. And among these is the evil in question. Our people, at first, oppose all distinctions whatever as odious and aristocratical; and then, presently, seek with avidity such as remain accessible. At first, they denounce colleges; and then choose to have a college in every district or county, or for every sect and party—and to boast of a college education, and to sport with high sounding literary titles; as if these imparted sense, or wisdom, or knowledge. How long this puerile vanity will continue in vogue, it is not easy to foresee.

Our farmers ought, beyond all question, to be liberally educated; that is, they ought to have the best education that is attainable. I do not say that every farmer ought to go to college, or to become a proficient in Greek and Latin. I speak of them as a class: and by a liberal education, I mean such a course of intellectual discipline as will fit them to sustain the rank which they ought to hold in this republic. They are by right the sovereigns of the land, because they constitute an overwhelming majority. Why do they not then, in fact, rule the land? Because, and only because, they are too ignorant. And thus they sink into comparative insignificance: and suffer themselves to be used as the mere instruments of creating their own masters, who care as little for their real welfare as if they were born to be beasts of burden. Were it possible, I would visit every farmer in Tennessee, who is not already awake, and endeavor to arouse him from his fatal lethargy, by every consideration which can render life and liberty desirable; and urge him to reclaim his abandoned rights and his lost dignity, by giving to his sons that measure of instruction which will qualify them to assert and to maintain their just superiority in the councils of the state and of the nation, like men proudly conscious of their intellectual as well as physical power.

The same general remarks apply to mechanics and to all the laboring classes, in proportion to their numbers. An education, even of the highest order, may be as valuable to them as to others. In our free country, a farmer or mechanic, with equal talents and intelligence, would be more likely to become a popular favorite, than either a lawyer, or the well-bred heir of an opulent patrician family. Suppose a farmer could speak as well, write as well, appear as well versed in history, geography, statistics, jurisprudence, politics, and other matters of general and local interest, as the lawyer—would he not stand a better chance of being elevated to the highest, most honorable, and most lucrative offices?

The grand bereavement on the subject of education seems to have arisen from the usage which obtained at an early period in modern European society, and which many centuries have sanctioned and confirmed, namely:—that a learned or liberal education was and is deemed important only for a liberal profession, or for

gentlemen of wealth and leisure. Hence the church, the bar, and the medical art, have nearly monopolized the learning of the world. Our people reason and act in accordance with the same absurd and aristocratic system. The *cui bono* is upon every tongue. "What good, it is asked, will college learning do my son? He is to be a farmer, a mechanic, a merchant." Now, I would answer such a question, in the first place, directly, thus:—"A college education, or the best, most thorough and most extensive education that can be acquired, will be of immense benefit to your son, simply as a farmer, mechanic, merchant, manufacturer, sailor or soldier." And I would patiently endeavor to show him how, and in what respects; but I will not attempt to illustrate such truisms at present. But, in the second place, I would reply to my plain friend's interrogatory, thus: "Educate your son in the best manner possible, because you expect him to be a MAN, and not a horse or an ox. You cannot tell what good he may achieve, or what important offices he may discharge in his day. For aught you know, he may, if you do your duty by him, become the President of the United States. At any rate he has reason and understanding, which ought to be cultivated for their own sake. Should he eventually live in the most humble retirement, and subsist by the hardest manual labor, still he may enjoy an occasional intellectual feast of the purest and most exhilarating kind." If all our laboring fellow citizens could relish books, and should have access to them, what a boundless field of innocent recreation and profitable entertainment would always be at hand and within their reach! What a flood of cheering light and happiness would be shed upon the dark path, and poured into the bitter cup of millions of rational, immortal beings: who, at present, rank but little above the brute in their pursuits, habits and enjoyments!

FORMATION OF SOIL.

The first inroads of fertility on barrenness are made by the smaller lichens, which, as Humboldt has well observed, labor to decompose the scorified matter of volcanoes, and the smooth and naked surfaces of sea deserted rocks, and thus to "extend the dominion of vitality." These little plants will often obtain a footing where nothing else could be attached. So small are many that they are invisible to the naked eye, and the decay of these when they have flourished and passed through their transient epochs of existence is destined to form the first exuvial layer of vegetable mold; the successive generations give successive increments to that soil from which men are to reap their harvests, and cattle to derive their food; from which forests are destined to spring, and from which future navies are to be supplied. But how is this frail dust to maintain its station on the smooth and polished rock, when vitality has ceased to exert its influence, and the structure which fixed it has decayed? This is the point which has been too generally overlooked, and which is the most wonderful provision of all: the plant, when dying, digs for itself a grave, sculptures in the solid rock a sepulchre in which its dust may rest. For chemistry informs us that not only do these lichens consist in part of gummy matter, which causes their particles to stick together, but that they likewise form, when living, a considerable quantity of oxalic acid; which acid, when by their decay set free, acts upon the rock, and thus is a hollow formed in which the dead matter of the lichen is deposited.—Furthermore, the acid, by combining with the lime-stone or other material of the rock, will often produce an important ingredient in the vegetable mold; and not only this, the moisture thus conveyed into the cracks and crevices of rocks and stones, when frozen rends them, and by continual degradation [disintegration] adds more and more to the forming soil.—Successive generations of these plants successively perform their duties, and at length the barren breakers, or the pumice plains of a volcano, become converted into fruitful fields.—*Prof. Burnett*.

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals,—viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	300
Do 2 " " Do "	250
Do 1 1/2 " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each. *Half Blood and upwards*.—A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenth Durham Shorthorn very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$100.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address—**L. I. HITCHCOCK,**

Amer. Fur. Office.

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale.

Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life,) is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also,—A young JACK, a son of Don Carlos, 4 years old, 45 inches high, well made, stout and promising, of same color as his sire—price \$200.

Also,—A full sister of the last, 3 years old, 44 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

L. I. HITCHCOCK,

Ap. 26—tf. Amer. Farmer Establishment.

TWO IMPORTED MALTESE JACKS FOR SALE.

These animals were purchased in Malta in June, 1852, for two officers of the U. S. ship Concord, in which they were imported. The selection was left to one of the best judges in the island, who advertised three months previous to purchasing, for the largest and best bred Jacks, without regard to cost—more than one hundred were offered before a choice was made. They are now about three years old, and stand, one 13 1/2 and the other 13 1/4 hands high, and will yet grow three or four inches; their color is black with fawn nose, eyes and belly. In size, action and vigor, they were believed to be unsurpassed by any Jacks in Malta, and they have been pronounced by good judges, the finest ever brought into the United States. It is deemed unnecessary to say any thing about the superiority of the Maltese Jacks, it being well known that they are of the high bred stock of Persia and Arabia.

These animals may be viewed and every information respecting them, may be obtained, by applying to **L. I. Hitchcock**, American Farmer establishment, Baltimore. The price is \$600 each.

TO VINE DRESSERS.

The Subscriber, wishing to engage a Vine Dresser to take charge of a flourishing and fruitful Vineyard, offers the most favorable terms to a person who can furnish testimonials of a good character.

For particulars apply to **L. I. HITCHCOCK**, American Farmer Establishment, or to the undersigned by letter, addressed to Brown's Mills, Millin Co. Penn.

May 24. 1855. **JOSEPH HENDERSON.**

HERBEMONT ON THE VINE AND WINE MAKING

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States. By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents.

IMPROVED DURHAM SHORTHORNS.

Several young BULLS got by Bolivar out of selected cows,—one nearly two years old, two yearlings, and two spring calves,—for sale at the Epsom Farm, seven miles and a half from Baltimore, on the York Turnpike road.

The bull Bolivar was bred by J. Whitaker, from the best stock in England, and imported by J. H. Powell, Esq. April 12, 1855.

HARVEST TOOLS, WHEAT FANS, &c.

SINCLAIR & MOORE, have in store, and are manufacturing a general assortment of HARVEST TOOLS, among which are

100 WHEAT FANS, double and single geared.

300 Grain CRADLES, with Seythes complete. This article is made of the best and most durable materials, and will be warranted as such.

50 doz. Grass and Grain SNEATHS.

30 do. Hay and Manure FORKS.

30 do. RAKES and Wooden tined FORKS.

SEYTHES and Sneaths, hung ready for use.

SICKLES, English and American Seythe Stones, Strickles, &c. &c.

Their Stock of CASTINGS, Agricultural Implements, Garden Tools and SEEDS, is as usual full and complete.

Also, just received from Europe, two bales, containing Lucerne and Ray Grass, Cabbage, Radish, Lettuce, and many other valuable SEEDS of last year's growth. From the appearance of this lot of Seed, and the respectability of the establishment from which they were imported, they can with the greatest confidence recommend them.

May 24.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street.

Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—Sales of Howard Street flour have been made at various rates embraced by our quotations. Probably \$5.56 may be considered the average store price, and \$5.37 1/2 the wagon price. Wheat has declined, and corn advanced a trifle, but the variations are too unimportant for consideration.

Tobacco.—Seconds, as in quality, 3 00 a 5 00; do. ground leaf, 5 00 a 9 00;—Clasp, common, 3 00 a 5 00; brown and red 4 50 a 6 00; fine red, 6 00 a 8 00; wrappery, suitable for segars, 6 00 a 15 00; yellow and red, 9 90 a 15 00; yellow, 16 00 a 20 00.—Fine yellow, 18 00 a 25 00;—Virginia 4 00 a —.—Rappahannock, 3 00 a 4 00.—Kentucky, 3 50 a 8 00. The inspections of the week comprise 406 hds. Md.; 141 hds. Ohio; and 9 hds. Penn.—total 646 hds.

Flour.—Best white wheat family, \$6 75 a 7 25; super Howard-street, 5 50 a 5 62 1/2; city mills, 5 75 a —; city mills extra 6 00 a —;—Corn Meal, bbl. 3 62 1/2;—GRAIN, best red wheat 1 12 a 11 8, white do. 1 22 a 1 25;—Corn, white 63 a 64, yellow, 64 a 65;—Rye, 68 a 70;—OATS, 37 1/2 a 41;—BEANS, 75 a 80;—PEAS, 65 a 70;—CLOVER-SEED 8 00 a —;—TIMOTHY, — a —;—ORANGE GRASS 3 00 a —;—Tall Meadow Oat Grass 2 00 a 2 50;—Herd's, — a —;—Lucerne — a 3 7 1/2 lb.;—BARLEY,—Fines 1 50 a 1 62;—Cott. Va. 11 1/2 a 13;—Lou. 12 1/2 a 14;—Alab. 11 1/2 a 13;—Tenn. 11 a 12 1/2;—N. Car. 12 a 13;—Upland 12 1/2 a 13 1/2;—Wmsey, hds. 1 1/2 a 1 29 a;—in bbls. 31 a 32;—Wool, Washed, Prime or Saxony Fleece 45 a 50; American Full Blood, 38 a 42; three quarters do. 33 a 38; half do. 30 a 33; quarter do. 28 a 30; common 25 a 28. Unwashed, Prime or Saxony Fleece, 25 a 30; American Full Blood, 22 a 25; three quarters do. 20 a 22; half do. 18 a 20; quarter do. 16 a 18; common, 16 a 18. Hemp, Russia-ton, \$195 a 205. Country dew-rotted, 6 a 7 c lb. water-rotted, 7 a 8 c;—Feathers, 37 a 37 1/2;—Plaster Paris, per ton. — a 1 25; ground, 1 50 a — bbl. Iron, gray pig for foundries per ton 33 00 a —; high pig for forges, per ton 25 00 a 30 00; bar Sus. per ton, 75 00 a 85 00.—Prime Beef on the hoof, 5 75 a 6 50.—Oak wood, 2 56 a 2 75; Hickory, 4 00 a 4 50; Pine, 2 00.

CONTENTS OF THIS NUMBER.

Editorial: Silk Filature to be established in Baltimore.—Sale of the late Mr. Meade's Stock.—Public Sale of Wool in Boston.—Exhibition of Maryland Horticultural Society.—The relative Advantages of Deep and Shallow Ploughing.—Raising Potatoes more Profitable than Corn and Wheat.—Raising Peas for Swine.—Two Crops of Potatoes produced in one year off the same ground.—Culture of Ruta Baga.—On the means of Prolonging the Valuable Varieties of Fruits, by Thomas A. Knight, F. R. S.—New and Desirable Flower Garden Plants.—Seeds from Com. Porter.—On the making of Raspberry and Strawberry Cordials, Cider and Wine; also observations on the growing of Sugar Cane in S. Carolina.—Absorbent Properties of Potash; Ploughing in Dry Weather.—A Machine to turn Hay, &c. into Cash.—New Cement.—Education of Farmers.—Formation of Soil.—Prices Current of Country Produce in the New York and Baltimore Markets.—Advertisements.

The American Farmer,

Edited by GIBSON B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum; due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect AT THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

5. DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "L. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, JUNE 14, 1833.

EXHIBITION OF THE HORTICULTURAL SOCIETY OF MARYLAND.—We were delighted, on Tuesday and Wednesday last, with the splendid exhibition of our infant Horticultural Society. It surpassed our expectations immeasurably; not that we saw plants or other objects that we did not know existed here, but that we did not expect to find our amateur horticulturists and florists so speedily and spiritedly enlisted in the cause. It is true, there are a few rare plants in some of the northern cities, which were not at the exhibition, but take it "for all in all," and as a first effort, it was creditable to our city, to our horticulturists, and especially to the committee for the good taste displayed in the arrangement of the plants.—The room, the musical saloon of the Athenæum, is the best in the city for such an exhibition, and the committee availed of all its advantages with great judgment and skill. We were gratified to see several eminent horticulturists and other gentlemen from other cities in the room, among them, Col. Carr and his son, of the celebrated Bartram Botanic Gardens of Philadelphia; Mr. Parker, of the same city; Mr. Barnitz, of York, Pa. and others.

We expect a detailed account of the exhibition from the chairman of the Committee of Arrangements, and, therefore, shall not attempt particulars. The season was rather unfavorable for flowers, the spring bloom having passed, and that of summer not sufficiently advanced for much display. Yet there were some splendid flowers, among them several fine Cactuses, and Amarylises—the *A. Johnsoniænsis*, exhibited by Samuel Feast, was the finest exotic plant in bloom, in the collection. Mr. Pearce, of Washington, exhibited some of the finest lemons, citrons, and oranges, we ever saw, and the gooseberries of Isaac McKim, Esq. were very conspicuous. Mr. Sam'l Feast, also exhibited some raspberries, from plants raised by him from seed, that were superior to any we ever before saw.—They are very early, large, firm, and of fine flavor. For these raspberries, Mr. Feast received the first premium plate, valued at \$20. Without doubt, the spirit of horticultural improvement has been aroused from its lethargy in Baltimore, and we may now expect to see our city among the first in the union, for useful and ornamental horticulture.

At 12 o'clock on Wednesday, an address was delivered to a crowded audience, in the saloon, by John P. Kennedy, Esq. We know not how to speak of it in terms sufficiently expressive of our feelings. It has been our vocation to read addresses of this kind for some seven years, during which time we have read some hundreds, but we never before had the pleasure of listening to, or of reading one equal to that of Mr. Kennedy. For appropriateness of remark, aptness of allusion, elegance of diction and enunciation, and above all, for beautiful classical illustration, it seems to us to have been unrivalled. We hope to be able to present the address to our readers next week, when we feel assured of their concurrence in all we have here said of it.

The following letter from Mr. Morris to Mr. Hitchcock, will account for the failure of the Fellenberg Institution, some time since established at Bolton Farm. The duty devolved on us by our peculiar situation, of communicating to Mr. Morris the information which led to the dissolution of the school, was one of the most disagreeable we ever performed; but where duty led, we could not hesitate to follow. We hope most sincerely that the patriotic labors of Mr. Morris, will ultimately be crowned with success; for, in his case, the remark of Virgil, quoted by him, is indeed, most true—"Sic vos non vobis," &c.

We would remark that the "general place of reference," &c. which Mr. Morris considers so necessary, has

been one of the objects of Mr. Hitchcock's Agency Establishment, from the commencement, and that he devotes particular attention to it.

Bolton Farm, near Bristol, Penn }
L. I. HITCHCOCK, Esq. May 31, 1833. }

Dear sir.—Your obliging favor of the 27th inst. was not received by me until yesterday, having been mislaid to the post-office, Burlington. I recognise, with peculiar pleasure, in it and its annexed advertisement, the very important connection of a General Agricultural Establishment with the publication of the American Farmer. Of this union permit me to express my particular sense of the great public benefit, and my hope that it will become as productive to yourself as its obvious utility merits.

The late Fellenberg Institution, which was established, at my suggestion, on Bolton Farm, and was conducted for some time in such a manner as to afford me the most conclusive proofs of its peculiar adaptation to our country, finally failed here, in consequence of the information communicated in August, 1831, by yourself and Mr. Smith, relative to the person to whom was committed its most important details.—R. L. Colt, Esq. of Baltimore, was present at the investigation, and its result, to which your information led; his high respectability of character, with that of other gentlemen who attended the investigation, sanctioned the conclusions which were adopted on the subject. The superintendent, alluded to, was dismissed; and the Institution at Bolton was soon after closed, for want of a suitable practical superintendent.

The seeds, however, of great and permanent utility were sown at Bolton, and the harvest will be reaped after many days, though not perhaps by those who have sown the seed: *sic vos non vobis melificatis*.

Institutions, in different parts of the United States, are, nevertheless, increasing, under various names and modifications, on the principles of Fellenberg, uniting intellectual and moral culture with useful agricultural, manual and mechanical labor, and from the results of these institutions, we shall soon find, as you suggest, that "the farm, the garden and the workshop will be considered the best schools for the preparation of useful and independent members of our republic." Combined education and industry can alone banish intemperance, ignorance and idleness from our rural population, the only pure source of the sovereign power of the people.

While the publication of the Farmer gives the information requisite to form practical men, your establishment of a general depot for every description of stock, machinery, implements, and seeds, seems calculated to furnish all that can be required by the agricultural community, except, perhaps, (permit me to observe,) what is a most essential want in every part of the United States, that is a general place of reference, where might be found, or from which reference might be made, to persons qualified for the situations of tenants, overseers, superintendents of all the descriptions of farms, dairies, stocks of cattle, gardeners, &c. &c. and to which all such persons, especially foreigners, might apply for places. With most sincere wishes for the success of your new establishment, I am, truly, your ob't serv't and friend.

ANTHONY MORRIS.

SOAP LEY has been accidentally discovered by a soap boiler to be excellent for garden walks or house yards. He spread in a wet state the black sulphurous residuum of the ley tubs on the alleys of his garden—which would not raise any grass or weeds afterwards, nor permit any growth within some inches of the place.—Delighted with the discovery, he had merely to put a covering of the sand over the refuse to obtain the finest walks possible—and having had occasion to repave his yard, he used the like soft refuse, instead of mortar, which soon hardened, and cemented the stones so well that the heaviest carriages occasioned no disadjustment.—*Silliman's Journal*.

PRIZE ESSAY.—We learn from the Richmond Enquirer, that the premium of thirty dollars, offered by the editor of the "Virginia Farmer," for the best essay to be entitled "Agriculture in Virginia," has been awarded to C. W. Gouch, Esq. of Henrico county.

The essay will speedily be published, and, we need scarcely say, it will be immediately transferred to our columns—the name of the author being a sufficient guaranty for the requisite qualifications.

RAIN.

June 1, 1833.

Mr. SMITH: The depth of rain, which fell during the last month, as indicated by the rain gauge, kept on Beechfield farm, the property of James Beacham, Esq. four miles from the city of Baltimore, on the Frederick road, was 5 12-100 inch.

THOMAS SMITH, Manager.

CHICK IN THE EGG.—The hen has scarcely sat on the egg twelve hours, when we begin already to discover in it some lineaments of the head and body of the chicken that it is to be born. The heart appears to beat at the end of the day; at the end of forty-eight hours, two vesicles of blood can be distinguished, the pulsation of which is very visible. At the fiftieth hour, an auricle of the heart appears, and resembles a lace, or noose folded down upon itself. At the end of seventy hours we distinguish wings, and on the head two bubbles for the brain; one for the bill, and two others for the forepart and hindpart of the head—the liver appears towards the fifth day. At the end of one hundred and thirty-one hours, the first voluntary motion is observed. At the end of one hundred and thirty-eight hours the lungs and stomach become visible—at the end of 142, the intestines, the loins, and the upper jaw. The seventh day, the brain, which was slimy, begins to have some consistence.—At the 160th hour of incubation, the bill opens, and the flesh appears in the breast. At the 194th, the sternum is seen, that is to say, the breastbone. At the 210th, the ribs come out of the back, the bill is very visible, as well as the gall bladder. The bill becomes green at the end of 236 hours; and if the chick is taken out of its covering, it evidently moves itself.—The feathers begin to shoot out towards the 240th hour, and the skull becomes grisly. At the 264th the eyes appear. At the 288th, the ribs are perfect. At the 331st, the spleen draws near to the stomach, and the lungs to the chest. At the end of 355 hours, the bill frequently opens and shuts; and at the end of 451 hours, or the 18th day, the first cry of the chick is already heard—it afterwards gets more strength, and grows continually, till at last it sets itself at liberty, by opening the prison in which it was shut up. Adorable wisdom of God! it is by so many different degrees that these creatures are brought into life. All these progressions are made by rule! and there is not one of them without sufficient reason. No part of its body could appear sooner or later, without the whole embryo suffering, and each of its limbs appear at the most proper moment. This ordination, so wise, and so invariable in the production of the animal, is manifestly the work of a Supreme Being.

FOREIGN MARKETS.

LIVERPOOL COTTON MARKET, May 9.

Sales on the 4th, (Saturday,) about 1500 bags, without change in prices. 6th, about 2000 bags, no change. 7th, about 1000, no change. Stb, 1500 bales, viz. 200 Brazils in Marahams at 9d to 9½c; and Bahais at 8½d; 50 Egyptians, 10d to 10½d; 50 Surats, 5½d; and 1200 in American descriptions, from 6½d to 8d. 9th, we have had a very steady cotton market to-day, and the sales amount to upwards of 3000 bags, at full prices, 1300 of which have been taken for export.—In Baltimore flaxseed small sales have been made for sowing, at 72s 7d to 75s.

AGRICULTURE.

(From the Northern Farmer.)
CULTURE OF WHEAT.

While New England is, to so very great an extent, dependent on the southern and western states for her supplies of flour, any inquiries which might result in the discovery of the causes, which have rendered either the soil or climate of so considerable a section of the country unfavorable to the culture of wheat, could not be uninteresting to our farmers. That a great change has taken place in this part of the country in relation to the culture of wheat, there can be no doubt. Forty years ago, when our lands were comparatively new, wheat was a certain and profitable crop. The same lands which then produced abundantly, cannot by any mode of culture now in practice, be made, in ordinary seasons, to produce enough of this grain to defray the expenses of cultivation. But are we therefore to conclude, that our lands have, by this comparatively short period of cultivation, become exhausted of that principle which forms the proper food of this plant, when the lands of Europe, which have been in a state of cultivation, probably for more than eighteen hundred years, still produce wheat in abundance? Or, are we to attribute the general failure of this crop to the ravages of the insect tribes? or, to the want of that skill in the culture of this plant, which seems to be abundantly possessed by the English husbandman, provided success be considered as evidence of skill? Whatever may be the cause which has produced this influence, it is certain that the effect exists.

Doctor Dwight, president of Yale college, a gentleman possessing habits of the closest observation, and with great powers of discrimination, after having travelled much in New England and the state of New York, previous to the year 1822, found the farmers at that time laboring under the same discouragements in relation to the culture of wheat, which now prevail, though, perhaps, not to so great an extent. As the result of his investigation at that period, he says:

"The reason why the lands in New England, which formerly yielded wheat, surely and plentifully, suffer at the present time such injuries from the blast, as in a great measure to discourage farmers from attempting to cultivate it, has been anxiously and extensively sought for, but not it is believed, satisfactorily discovered. From my own observations and inquiries, I have been induced to attribute this evil to the efficacy of animal manure. This subject has been already mentioned in my observations on the county of Worcester: it shall now be resumed.

"The manner in which wheat is generally blasted in New England, appears to me very evidently to be this: During the months of June and July, when the kernels of wheat in the different climates of New England, are in the milk, the vegetation is far more rapid than in most countries of Europe.—Whenever the season at this period is both moist and hot, the rapidity becomes extreme. The vegetable juice, ascending then in too great quantities, and with a new celerity, moves with difficulty through the vessels of the stock, regularly lessening towards the neck, and at that time so tender as to be easily ruptured, bursts them in various places, particularly at the neck, and flows out upon the surface of the stem. When it first exudes, it is very sweet to the taste; and has hence been commonly supposed to be the residuum of a particular kind of dew, called by the farmer honey-dew. Had any farmer recollected, what he cannot fail to find, where he finds a honey-dew, that it never appears on any thing beside living vegetables, and that, if it were a dew, it must be found equally on every other substance exposed to the atmosphere, he would certainly have determined, that it was merely the sweet juice of the vegetable itself. When this juice has pervaded the stalk, it soon becomes sour in the sunbeams; then so acrid, as to corrode the stalk,

and finally a rust, (as it is commonly called,) of a brown hue, and an offensive smell.

"Animal manure beyond any other, accelerates vegetation. Wheat, nurtured by this manure, grows with so much rapidity, and with so slender a stalk, that, in the agricultural language of this country, it lodges not unfrequently (i. e. falls under the pressure of wind or rain) by its own weight, and never recovers its original position. This dangerous process is peculiarly advanced by the use of this manure; and the rapidity of vegetation, otherwise too great, is by this substance rendered still greater. Hence all fields, where this manure is employed, are peculiarly exposed to blast. For a few years after lands are dressed with it, the evil is so evident to the eye of common observation, as to be not unfrequently believed to exist by some farmers, and suspected by others. Were every season hot, and wet during this period, it would, I doubt not, have long since been generally realized and acknowledged. But as in some seasons these months are cool and dry, and those fields which have been dressed with this manure, then yield wheat successfully; and as in the most unfavorable season, lands dressed in a different manner, are also subjected to the blast; the question has, hitherto failed of any answer, which has been generally satisfactory.

"The reasons which have induced me to adopt the opinion here alleged, are principally the following:

"1. All the lands in this country, which were not too wet, originally yielded wheat easily, surely, and so far as they were rich, abundantly. The inhabitants of Northampton, for many years paid their public tax in wheat, and this wheat grew on the very lands, where for a long period it has been supposed to be so uncertain an object of culture, as to be scarcely worth the attempt, i. e. on intervals.

"2. New lands yield wheat perfectly well in most parts of this country at the present time. Some farmers believe, that there is such a change wrought by time, either in the climate or in the soil, independently of the proper effects of culture, that the blast is to be attributed to this change. Although this is a mere supposition, supported by no evidence, it has still had its weight. But it is entirely refuted by the fact, mentioned under this head. Lands in the same circumstances yield wheat as abundantly at the present time, as at any former period. It deserves to be remarked, that all the intervals along the Connecticut have furnished sure crops of this grain for a considerable time after they first began to be cultivated.

"3. Lands dressed with ashes, now furnish fine crops of wheat, which is rarely or never blasted. The only reason why the crops on new lands are so safe from the blast, is that they are covered with vegetable mold, another name for vegetable manure; and so long as the efficacy of this manure lasts, are dressed with no other. It is the universal tendency of this mold to produce great crops; but it produces them by a gradual and moderate vegetation. Ashes, which are the same manure in another form, produce the same effect in exactly the same manner. Accordingly, although the crop of wheat, yielded by grounds dressed with ashes, is abundant, yet the stalk is firm, and strong; much stronger, but much shorter than that produced by animal manure, and equally safe from lodging, and blasting, as that which grows on vegetable mold.

"It ought to be observed, that in grounds where the vegetable mold is very deep and abundant, wheat grows so rapidly as to be universally blasted. That this effect is solely derived from the redundancy of this manure is certain, because the same lands after the cultivation of a few years yield wheat perfectly well.

"4. In various instances, which have fallen within my knowledge, wheat sown after clover has been perfectly free from any injury by the blast; and that on intervals, and other lands most liable to this injury.—Here vegetable manure has been employed in another form; yet the same effect has been produced.

"5. Lands, dressed with gypsum, have been equally favorable to wheat. This good effect has, however, been commonly produced through the medium of clover; the gypsum having been first employed for the production of this plant, and the wheat having been sown after the clover had been ploughed in.

"6. Fields manured with the white fish, have yielded wheat universally in great abundance, and with almost absolute certainty. This is indeed animal manure also; but very different from that, which I have intended by this phrase above; viz: that of stable and barn yard. The white fish is a species of herring, very fat and oily, and remarkably favorable to vegetation of every kind, which is the object either of agriculture or horticulture. I have mentioned this fact, that the evil complained of, has its origin neither in the soil, nor in the climate, but in the particular mode of cultivation, which I have mentioned as its proper cause.

"7. The lands in Pennsylvania, which yield plentiful crops of wheat, are regularly dressed with lime, or gypsum; and neither here, nor in those old settlements in the state of New York, where this grain is least exposed to the blast, are cattle very numerous. Of course, the kind of manure which I suppose to be noxious to this plant cannot abound in these countries. I am informed also, that where this manure is used, it is generally mixed with other substances in a compost; and converted, either partly, or wholly, into mold, before it is employed as a dressing. It ought also to be observed, that a great part of the wheat lands in these countries are clay; and that the process of vegetation may be therefore materially different from that which exists in New England, where the soil is principally loam with the mixture of gravel. It is, however, said, that in Pennsylvania their crops fail, where they are unable to dress their lands with lime, or gypsum. It is also said, that the lands along the Mohawk river, which have heretofore yielded wheat with great certainty, as well as luxuriance, are gradually becoming less and less fitted for this kind of culture."

I have been informed that at Newbury they have lately adopted a new kind of husbandry, by means of which the crops of wheat are no less sure and prosperous than they were formerly. What this mode is, I have not, however, been able to learn.

In my own belief, animal manure, produces this noxious effect long after it has ceased to enrich the soil. Although its influence has in this case become small, yet so far as it extends, it is mischievous; and may at the dangerous period above mentioned accelerate a growth, at least sufficiently rapid, otherwise, so as to produce the evil in question. Thus, I consider grounds, long devoted to pasturage, as being injurious to the culture of wheat, as really, though in a less degree, as those which are manured from the stable in form.

(From the Genesee Farmer.)
CULTURE OF FLAX.

Rochester, May 8, 1833.

Having resided in this country a number of years, and frequently observed the manner of cultivating flax—its coarseness of texture, length, &c. when compared with the flax of Germany or Ireland, I have thought a few observations of the culture as generally practiced by the most experienced flax growers of Ireland, would attract the attention of some of our practical farmers. Although my occupation is not to wield the axe or hold the plough, but the feathered goose-quill my favorite, yet I hold it a duty we owe one another to publish and inform all that lays in our power, of any new improvement either in agriculture, horticulture, or the mechanic arts; for this object, I have made the following remarks, which I shall class under different heads.

I. PREPARATION OF THE LAND.—The potato land of last year, which has been well manured, and borne but one crop of potatoes, being most likely to produce

a prime crop of flax, a portion should be set apart for that purpose, and ploughed as early in the spring as possible, if it can be done late in the fall the better; previous to sowing, the land must be made very fine, by a second ploughing and harrowing; all lumps must be broken, stones picked off, and all the weeds taken off.

II. CHOICE OF THE SEED.—This should be of a bright color, plump, and which, when bruised, appears of a light or yellowish color, oily and fresh in the heart; and such as is sweet, both to the taste and smell, may be depended on as good.

III. SOWING.—The seed should be sown with an even and careful hand; any time from the first of April to the first of May, perhaps the fifteenth to twentieth, is not too late in ordinary seasons for this country. (If clover or grass seed is to be sown, it should be done at the same time, the grass sower following the flax sower.) The seed to be sown broad cast and covered lightly with the harrow. The land is then to be water furrowed, by running the plough up or down at the distance of every six feet.

IV. WEEDING.—This process should never be omitted. When the flax is well up above the ground, say four or five inches, it should be carefully weeded by women and children, who may stand or sit on the bed, and by all means have the weeds carried clear off the ground. The crop is at this period to be rolled, (if practicable); the flax will be much improved by this process, and experience has shown that flax grows much faster after being weeded than it does before.

V. PULLING.—The flax is fit to pull when there is a light yellow tinge throughout. If not pulled in time, the flax will be coarse. Previous to pulling, bands of rushes should be gathered, dried, and well beat for binding the flax with. Any flax which grows short and branching, should be left to ripen more in order to perfect its seed, it being fit for little else. The pullers should catch the flax about the middle, and when they have their hands full, to pull up, and to the standing crop; when bound, it should be left for two days in this state to dry. If very fine flax is wanted, it should be pulled at an earlier stage; and if there is a material difference in the fineness of parts of the crop, the different qualities should be kept separate.

VI. RIPPLING.—Where it is intended to save the seed, and not to look for a crop of good flax, the seed should be taken out, by taking a handful of the flax, and drawing it through a ripple; an instrument like a rake, or a single row of a hackle, but wider than the latter. The seed should be well dried in the sun, then thrashed, sieved and winnowed; and put in a dry place for the next year.

VII. BAGGING AND WATERING.—Let the flax be bound into small sheaves with the rush bands, the root end put downwards in the water, and covered with ferns or light brush. The water should be stagnant; bog water when to be had is to be preferred. The softer the water, the speedier the operation, and the deeper the water the better. The flax is generally sufficiently hogged in fifteen days. It is fit to take out, if the stalk when broke in the hand, parts freely from the flax. It should be examined every day after ten days, as some waters act more speedily than others; the same water will not do again. When sufficiently watered, the flax should be taken out and gently rinsed: it should be very carefully and gently handled.

VIII. GRASSING.—The flax should be taken to a clean lay field, or to a meadow cleared of hay; the rush bands collected, and put to dry for next year, and the flax spread out very thin. It should be examined every day after it has been ten days out, tried as before—and when the flax comes off freely from the stem, which is then brittle, it is grassed sufficiently. It is then to be tied up in sheaves, and should be left out for a few days to dry; when it may be either stacked or boused; if stacked, it should be thatched to the ground, having first put a dry bottom under it.

IX. DRYING.—The flax should be well dried in

the sun on a warm day; and scutch it as soon afterwards as possible. Stoving is found prejudicial to the staple, and if resorted to, is to be used with the greatest caution, it being found to make the flax very brittle, dries up the substance, and makes the bleaching more difficult, and yields much less at the hackle.

LASTLY, TRY THE EXPERIMENT.—I have this object in view in publishing the above, to state the process as pursued, and found by experience to be best, by the flax growers of Ireland, from whence we derive such fine linen fabrics, and I hope some of our practical farmers will at least make use of any of the above suggestions, and publish their remarks. We have every description of soil and climate, but we are far behind in the improvement of such a domestic production as the flax, although Ireland is yearly indebted to this country for its seed. **HIBERNIA.**

(From the British Farmer's Magazine.)

ON SETTING WHEAT.

This is a method which is reckoned one of the greatest improvements in husbandry that was made during the last century.

It seems to have been first suggested by planting grain in a garden for mere curiosity, by persons who had no opportunity of extending the cultivation for profit. This was first attempted at Norwich, and a few years after by one of the largest occupiers of land in Norfolk, who set fifty-seven acres in one year. His success from the visible superiority of his crop, both in quantity and quality, was so great that in the following autumn he set three hundred acres, and has continued the practice ever since. This noble experiment established the practice, and was the means of introducing it generally among the intelligent farmers in a very large district; there being few who now sow any wheat, if they can procure hands to set it. It has been generally observed that although the set crops appear very thin during the autumn and winter, the plants tiller and spread prodigiously during the spring. The ears are indisputably larger, without dwarfish or small corn;—the grain is of a larger bulk, and specifically heavier per bushel than when sown. The lands on which this method is particularly prosperous, are either after a clover stubble, or on which trefoil and grass seed were sown the spring before the last. These grounds, after the usual manuring, are once turned over with the plough in extending flag or turf, at ten inches wide; along which a man, who is called a dibbler, with two setting irons somewhat bigger than ramrods, but considerably larger at the lower end, and pointed at the extremity, steps backwards along the turf, and makes the holes about four inches asunder every way, and one deep. Into these holes the droppers (women, boys, and girls) drop two grains, which are quite sufficient. After this, a gate bushed with thorn is drawn by one horse over the land, and closes up the holes. By this mode three pecks of grain are sufficient for an acre: and being immediately buried, are equally removed from vermin or the power of frost. The regularity of its rising gives the best opportunity of keeping it clear from weeds, by weeding or hand hoeing. Setting of wheat is a method peculiarly beneficial when corn is dear; and if the season is favorable, may be practised with great benefit to the farmer. Sir Thomas Beevor, of Hethel Hall, in Norfolk, found the produce to be two bushels per acre more than from the sown wheat; but having much less smaller corn intermixed with it, the sample is better, and always fetches a higher price, to the amount generally of two shillings per quarter.—This method, too, saves to the farmer and the public six pecks of seed wheat in every acre; which, if generally adopted, would of itself afford bread for more than half a million of people. Add to these considerations the great support given to the poor by this second harvest, as it may be called, which enables them to discharge their rents and maintain their

families without having recourse to the parish. The expense of setting by hand is now reduced to about six shillings per acre; which, in good weather, may be done by one dibbler, attended by three droppers, in two days. This is five shillings per day; of which, if the dibbler gives to the children sixpence each, he will have himself three shillings sixpence for his day's work, which is more than he can earn by any other labor so easy to himself. But if he have a wife who dibbles with him, and two or three of his own children to drop to him, his gains will then be very important, and enough to insure a plenty of candidates for that work, even in the least populous parts of the country. But the profit of this method, in seasons when seed corn is very cheap, or the autumn particularly unfavorable to the practice, must certainly be lessened.

This, then, is one of the improved methods of farming which the Agricultural Employment Institution ought to adopt. Transplanting wheat is another source of employment for the redundant poor, the beneficial results of which may be seen at the Exhibition of Arts, Charing Cross, sent there by Mr. E. J. Lance of Lewisham.

PERMANENT PASTURES.

There is one objection against lands newly laid down to grass, which both Sir John Sinclair and John Lorain seem willing to admit, namely: such grounds being softer than old pastures, are not so eligible for heavy cattle.

The late Judge PETERS, although he admits that "changing crops, or what is called *convertible husbandry* in which grass is only part of the rotation, would be found most suitable to the circumstances of [that] country," yet he appears to have been partial to old pastures. In his *Notices for a Young Farmer*, the remarks, "It will be difficult to keep an old weedy farm long in grass; and the plough must therefore be oftener used than a clean farm requires. Yet with compost as top dressings, and destruction of weeds, wonders may be performed in a grazing system. If you should be so fortunate as to conquer weeds and pests, and obtain a clean cover of the *Poa viridis* or green grass, it is not to be told how long your fields, with top dressings will continue without being disturbed by the plough, if scarified, when surface bound, by a proper instrument.

"The experiment of cleaning by tillage, and meliorating by manure, worn lands, and enable them to throw up grasses spontaneously, has decidedly succeeded, so as to ensure valuable crops of the appropriate kinds which finally establish themselves, after contending with intruders for a time."

From Dr. Mease's Eulogium on William West, it appears that, that eminent grazier was decidedly in favor of old pastures. "A permanent pasture was the object he aimed at, for he held it a principle that every country was blessed by a native permanent pasture grass.

"He had the satisfaction to see the complete success of the practice. For as the artificial grasses declined, the permanent native green grass took their place; and only required a repetition of the practice which caused its appearance, to insure its continuance; and for many years, he exhibited the only instance in the county, of an entire sward of green grass upon an upland farm; and of fields which had not been disturbed by the plough for upwards of thirty years."

In the latter case, it is evident that West's attention was entirely turned to grazing; but in this fine wheat growing district, very few, if any, of our farmers confine their attention to stock, generally deeming the *convertible husbandry* the most profitable.—Yet there are circumstances with us, in favor of retaining an old pasture field, which do not prevail in

**Poa viridis*, of Muhlenberg—*Poa pratensis*, of Linnæus—the spear grass of the Genesee country.

some other districts no manure to prevent its deterioration, is required—so fertile are our lands; and simply to convert it into meadow *without pasturing* for a year or two, will cure it of being *surface bound*.
A FARMER.

(From the Genesee Farmer.)

CUTTING OFF INDIAN CORN IN THE FALL.

Indian corn in the past season was remarkably backward in ripening; and having a field that I was anxious to sow at the proper time, I was under the necessity of cutting and removing the corn on the stalks while it was in a very green state. Several of my neighbors said that much of the crop would be lost, and indeed I was apprehensive of the consequences; but when we came to husk it, I was surprised to find it in so dry a state, and so free from moldy damaged ears; though much of it was so soft that we fed it out as soon as we could to our fattening hogs and beef cattle. Another field of Indian corn, in the same state, which we topped at the usual time, has not turned out so well, as there were more moldy ears.—Until that time I had always been an advocate for *topping*, and nothing but necessity induced me to try the experiment of cutting the green stalks at the ground.

The corn when cut off was not put into *stooks* [shocks] but placed round the field against the fence; and we think it probable that the ears would be less liable to mold in that situation than if they were bound up in *stooks*.

HORTICULTURE.

(From the London Horticultural Register.)

ON FORCING BULBS TO CAUSE THEM TO FLOWER IN WINTER.

Mere Hall, Feb. 20, 1833.

Being a constant subscriber since the commencement of the Register, I have, with several of my neighbors, hailed with pleasure, the first day of every month, feeling assured that your Magazine would bring us a fresh supply of important information, to add to our scanty stock of knowledge. I have sent for your insertion, if you think they merit it, a few remarks on my method of forcing bulbs, which I hope may be of some service to the more inexperienced portion of your readers.

Early in October, send for a quantity of Dutch bulbs, as narcissus, tulipa, hyacinthus, &c and previous to doing so, provide a quantity of mold, composed of

Two barrows full of well decomposed hot-bed dung,
One barrow full of fresh loam,

One do of vegetable or leaf mold,

One-quarter of a barrow full of fine sand.

These are to be well chopped, and mixed together, then lay the compost in an open shed, to dry a little before using. About the second week in October, pot the bulbs in the above soil, in pots proportioned to the size or sort of bulb. Fill all the pots with soil, and shake it down, but do not press it with the hand before commencing to plant the roots; then lay some clear sand on the soil, in the middle of the pot, and placing the bulb on the sand, gently press it down till within half an inch of the top. Care must be taken not to press with sufficient violence to injure the bulb, yet it must be left firm in the pot; for on these two things much depends, with regard to their growing freely.

After they are potted, and named or numbered, place them in a cucumber or melon frame, prepared after the following manner: Take out the soil, and lay on the old bed about two inches thick of fine ashes, level and make them pretty solid, on the top of this lay a quantity of sifted ashes, in which plunge the pots, making the ashes as firm about the pots as possible. After this is finished, cover the whole to the depth of eight or ten inches with dry light soil. Al-

ways choose a dry day for the purpose, and let every thing be dry that is used about plunging; or the bulbs will be liable to perish. Give air at all times in fine mild weather, but allow no wet or frost to enter the covering soil; at nights, the lights must always be on, and in severe weather closely covered down with mats; but if the nights are mild, the glasses may be tilted, to allow a little air.

In January, take them out of the frame, wash the pots, carry them to the stove for flowering; and give them regularly, a moderate supply of water, to assist them to flower strong. As the flower stalks advance in growth, tie them to neat green or white sticks; and if treated as above they will flower beautifully. Crocuses planted four or five in a pot, flower well when treated as above. I also beg to state, that Mr. J. Knight, of the Exotic Nursery, Chelsea, is supposed to sell as good bulbs, and as cheap, as any person in the neighborhood of London. F. F. ASHFORD.

(From the Genesee Farmer.)

VERNAL FLOWERS.

[In a letter to the Editors, dated May, 13.]

As the season advances, there is a considerable increase in the number of fine flowers. Among these we may reckon for the first part of this month the chalcidonian *Iris*, several kinds of *Paeonia*, the fish blossom or Judas tree, the double flowering almond, the Chinese purple *Magnolia*, the silver bell tree, the poet's *Narcissus*, the auricula, the *Dodecatheon*, and many varieties of the primrose or polyanthus. Many others scarcely inferior must be omitted, with some already mentioned which continue yet in bloom.

The chalcidonian *Iris*, is more interesting on account of its singularity than its beauty. It is not so readily increased as many other species of *Iris*; but it appears to be hardy, though mine has not been fully exposed in the open ground.

Last year my tree *Paeonia* (*P. moutan*) bloomed for the first time, and I felt disappointed, its beauty not equalling my expectations; but this season the flowers are truly superb. I cannot explain the cause of this difference, except that a slight deficiency in the vigor of some plants nearly destroys the beauty of the flowers. These are almost white, increasing to a reddish purple near the centre. It is not entirely double, for which it is the finer, as the yellow anthers dispersed among the petals, and the purple stigmas appear to great advantage. It is said that severe vernal frosts will destroy the flower-buds of this plant, if exposed, as it starts remarkably early in the season.

It is increased by suckers which originate near the base of the stem, but which acquire vigor very slowly when separated.

Paeonia tenuifolia has flowers of a beautiful red, but they are not always equally fine, perhaps on account of its strength being divided among many new stalks which spring from horizontal subterranean *suckers*. This species affords the only example that I have seen among *Paeonias* of this way of increasing.

Cereis canadensis, or the fish blossom, is a large shrub which is found native as far north as the fortieth degree of latitude. It is perfectly hardy in the Genesee country. Its blossoms are a light pink, and so crowded and so numerous as partly to hide the branches. Several travellers who have descended the Ohio river, in speaking of the most ornamental trees which they have seen on their passage, have given this the preference. It merits a place in every good collection.

The double flowering almond (*Amygdalus pumila*, *pl*) is an old resident of the gardens, and doubtless one of the most beautiful. It is increased by suckers, and grows well when budded on the peach tree. It is however subject to the attacks of the *Egoria* as well as the latter tree; and its branches are sometimes disfigured by gummy exudations, probably caused by the irritations of some other insect.

My purple Chinese magnolia (*M. obovata*) is a small shrub of singular appearance with large flowers of great beauty. It has bloomed this season for the first time. Though it stands in open ground, it had some protection in winter and it may be doubted if its large flower buds would abide uninjured in a less favored state.

The silver bell tree (*Halesia tetraptera*) though a native of Carolina is well suited with our climate.—Its blossoms are very numerous and of a silvery whiteness.

Narcissus poeticus is a very fine species: petals white, cups edged with red, are delicately fragrant. It flowers freely, not being subject to blast like some other white kinds.

The *auricula* is an old favorite of the gardeners.—I have slightly protected mine, but have never lost one through the severity of our seasons. They do best in a border shaded from the noontide sun; and rest very securely in winter under a cap of moss.—They flourish most in a highly manured soil. This species of *Primula* is a native of the Austrian Alps; and under cultivation has spread into varieties without number. An amateur has said that more beauty was concentrated in the auricula than in any other flower of the same size.

In the eastern parts of the United States, the northern limits of *Dodecatheon meadia*, varies not greatly from the latitude of Philadelphia, though near the Rocky Mountains it attains a higher latitude, and consequently is entirely hardy in the Genesee country. It is deservedly admired. The corolla of the common kind is a reddish purple, but there is also a white variety.

Dodecatheon integrifolium is a smaller species, but very nearly allied. Instead of having the "pale blue flowers" of Pursh, like the common variety of the other species, they are a reddish purple. All these plants are strictly *vernal*, the leaves disappearing early in summer.

(From the Genesee Farmer.)

CHESTNUT TIMBER.

Greatfield, Cayuga Co. 5 mo. 13, 1833.

My obliging correspondent D. Longstreth, partly, in consequence of some suggestions of mine, lately made a visit to the estimable author of *The Pennsylvania Farmer*, at his residence in Montgomery county, (Pa.) I wanted to ascertain some particulars relating to the growth and durability of chestnut timber, which I now present in an extract from his letter, dated in the second month last.

"I lately made a visit to Job Roberts, Esquire, and was much pleased with a fence he has constructed of stone posts and four good chestnut rails to each panel. It was all white washed. The rails are of the third cutting of chestnut which his father cut for the first time in the year 1777. This wood lot contains three or four acres, and at that time it was covered with the usual mixture of timber, but rather the larger part was chestnut. They obtained about seven hundred and fifty rails, which were made into a common fence on one side of this lot; and the suckers from the stumps were carefully protected from the cattle. The chestnut proved of quicker growth than the other trees, partly overshadowing them; and there being several suckers to a stump, at the age of twenty-two years the second cutting yielded more than three thousand rails.

"He commenced the third cutting of the chestnut suckers in 1823, and estimates them to yield about eight thousand rails. A part yet remains uncut, but it is evidently on the decline, and he is of opinion that twenty-five years is as long a time as they ought to stand. The trees are very tall and straight, some of them having made seven rail-cuts of eleven feet each. From one quarter of an acre of the best part of the lot, he cut nearly one thousand rails."

*Published in 1804.

To show the durability of good chestnut timber, he remarks, "the rails made from the *first cutting*, fifty-five years ago, are still in good condition."

In regard to the best time for cutting timber with a view to the *sprouting of the stumps*, he says "many proprietors of chestnut lots, on the great valley hills, are careful to cut their rails in the spring when the sap is beginning to flow freely,—as they have ascertained that the stumps will sprout more vigorously than if they were cut in mid-winter. We have cut chestnuts in the latter part of summer that have sprouted freely."

Nothing is said of the best time for cutting timber with a view to its *durability*. It is an old, and I am inclined to think a well founded opinion, that it ought to be cut previous to the rising of the sap in spring; but others have preferred the close of summer just before the fall of the leaf; and we are much in want of accurate experiments on this subject. I should be gratified to know at what season those rails were cut that have lasted fifty-five years.

I will select another paragraph from his letter: "In the year 1797 he had bored logs of the tulip poplar [or white wood] laid down to convey water from a spring to his milk house. Some of these are now beginning to leak; but in the mean time an entire young growth of the same kind of timber has sprung up, which is large enough to replace the old logs."

D. T.

RURAL ECONOMY.

(From the Farmer's Series of the Library of Useful Knowledge.)

GLANDERS IN HORSES.

The most formidable of all the diseases to which the horse is subject, is glanders. It is described by writers fifteen hundred years ago, and it was then, and is now, not only a loathsome, but an incurable disease; we shall, therefore, principally confine ourselves to the consideration of its symptoms, nature, causes, prevention, and degree of contagion, and these will afford much matter of interest to the farmer.

If we could obtain an authentic history of the glandered horse, we should find that in a majority of instances, if the disease were bred in him, he had been dull, off his feed, losing flesh, and his coat staring; and that these appearances had for several weeks preceded the characteristic symptoms of glanders.—These symptoms, however, may lead to, or be the causes of other diseases, or they may pass away, and the horse return to perfect health. That which would be considered as the earliest, and unquestionable symptom of glanders, would be an increased discharge from one or both nostrils; different from the discharge of catarrh, because it is usually lighter and clearer in its color, and more glutinous or sticky. When rubbed between the fingers it has, even in an early stage, a peculiar, clammy feeling. It is not discharged occasionally, and in large quantities, like the mucus of catarrh, but it is constantly running from the nostril.

It is a singular circumstance, for which no satisfactory account has yet been given, that when one nostril alone is attacked, it is in a great majority of cases, the near or left nostril. M. Dupuy, the director of the veterinary school at Toulouse, gives a most singular account of this. He says, that out of eight hundred cases of glanders that came under his notice, only one was effected in the right nostril.

This discharge, in cases of infection may continue, and in so slight a degree as to be scarcely perceptible, for many weeks or months before the health and capabilities of the horse seem to be injured. It will remain for a long time almost transparent, yet gluey; and then it will begin to be mingled with pus; retaining, however, its sticky character, and being rarely offensive in the early stages. The constant flow of this secretion, and its stickiness, with the absence of

enough either before, or during the discharge will be the only symptoms. In process of time, however, pus mingles with the discharge, and then another and a characteristic symptom appears. Some of this is absorbed, and the neighboring glands become affected; and if these be discharged from both nostrils, the glands within the under jaw will be on both sides enlarged. If the discharge be from one nostril only, the swelled gland will be found on that side alone. Glanders, however, will frequently exist at an early stage without these swelled glands, and some other diseases, as catarrh, will produce them. Then we must look out for some peculiarity about these glands, and we shall readily find it. The swelling may be at first somewhat large and diffused, but the surrounding enlargement soon goes off, and one or two small distinct glands remain; and they are not in the centre of the channel, but *adhere closely to the jaw on the affected side*.

The membrane of the nose may now be examined, and will materially guide our opinion. It will either be of a dark purplish hue, or almost of leaden color, or of any shade between the two; or if there be some of the redness of inflammation, it will have a purple tinge; but these will never be the faint pink blush of health, or the intense and vivid red of usual inflammation. Spots of ulceration will probably appear on the membrane covering the cartilage of the nose—not simply sore places, or streaks of abrasion, and quite superficial, but small ulcers usually approaching to a circular form, deep, with the edges abrupt and prominent. When these appearances are observed, there can be no doubt about the matter. Care should be taken, however, to ascertain that these ulcers do actually exist, for spots of mucus adhering to the membrane have been more than once taken for them. The finger should, if possible, be passed over the supposed ulcer, to determine whether it can be wiped away; and it should be recollected, as we have always hinted when describing the duct that conveys the tears to the nose that the orifice of that duct, just within the nostril, and on the inner side of it, has been mistaken for a cancerous ulcer. This orifice is on the continuation of the common skin of the muzzle which runs a little way up the nostril, while the ulcer of glanders is on the proper membrane of the nose above; and the line of separation between the two is evident on the slightest inspection.

It is proper to state that this discharge has continued unattended by any other disease, or even by ulceration of the nostril for two or three years, and yet the horse was decidedly glandered from the beginning, and capable of propagating the malady.

When ulcers on the membrane of the nose have appeared, the constitution will be evidently affected.—The horse will lose flesh; his belly will be tacked up; his coat will be unthrifty and readily come off; cough will be heard; the appetite will be impaired; the strength will fail; the discharge from the nose will grow more purulent, discolored, bloody and stinking; the ulcers in the nose will be larger and more numerous; and the air passages being obstructed, a grating, choking noise will be heard at every act of breathing. The lungs are now diseased; they are filled with tubercles or ulcerations; and the horse at length dies, an emaciated and loathsome object.

The symptoms frequently vary, and to a most puzzling degree. The discharge will be so slight as scarcely to be perceived, and known only by its stickings; and the glands will not be in the least degree enlarged. At other times a very small enlarged gland may be found, adhering to the jaw, and may be stationary month after month, and the surgeon may be told that there has never been discharge from the nose. He will, however, be wrongly informed, for it has most assuredly existed, although perhaps to no great degree, at some former period; and he will generally, without much difficulty, discover it then, although, perhaps, in so small a quantity that the groom will deny its existence; and he will principally satisfy himself with respect to it, by its gluey feeling.

Glanders have often been confounded with *strangles*, and by those who ought to have known better. Strangles are peculiar to young horses. The early stage resembles common cold, with some degree of fever and sore throat; generally with distressing cough, or at least frequent wheezing; and when the enlargement is beneath the jaw, it is not a single small gland, but a swelling of the whole of the substance between the jaws; growing harder towards the middle; and after a while appearing to contain a fluid and breaking. In strangles the membrane, of the nose will be intensely red, and the discharge from the nose profuse and purulent, or mixed with matter almost from the first; and when the tumor has burst, the fever will abate, and the horse speedily get well.

Should the discharge from the nose continue for a considerable time after the horse has recovered from strangles, as it sometimes does, there is no cause for fear. Simple strangles need never degenerate into glanders. Good keeping, and small doses of blue vitriol given internally will gradually make all right.

Glanders have been confounded with catarrh or cold, but the distinction between them is plain enough. Fever accompanies cold, and loss of appetite, and sore throat; the discharge from the nose is profuse, and, perhaps, purulent; and the glands under the jaw, if swelled, are moveable, and there is a thickening around them, and they are tender and hot. With proper treatment the fever abates; the cough disappears; the swellings under the throat subside, and the discharge from the nose gradually ceases, or if it remain, it is usually very different from that which characterises glanders.

A running from the nose, small in quantity, and from the smallness of its quantity drying about the edges of the nostril, and so presenting some appearance of stickiness, will in a few cases remain after severe catarrh, and especially after the influenza of spring; and these have gradually assumed the character of glanders, and more particularly when they have been accompanied by enlarged glands and ulceration in the nose. Here the aid of a judicious veterinary surgeon is indispensable: and he, perhaps, will experience considerable difficulty in deciding the case. One circumstance will principally guide him. No disease will run on to glanders, which has not, to a considerable and palpable degree, impaired and broken down the constitution: and every disease that does this will run on to glanders. He will look then to the general state and condition of the horse, as well as to the situation of the glands, the nature of the discharge and character of the ulceration.

The history we have given of the symptoms of glanders will pretty clearly point out its nature. It is an affection of the membrane of the nose. Some say it is the production of tubercles, or joint tumors in the upper cells of the nose, which may long exist undetected, and hard to be detected except by a scarcely perceptible running from the nostril, caused by the slight irritation which they occasion. These tubercles gradually become numerous; they cluster together, suppurate and break; and small ulcerations form. The ulcers discharge a poisonous matter which is absorbed, and taken up by the neighboring glands, and which with greater or less rapidity vitates the constitution of the animal, and is capable of communicating the disease to others. Other surgeons content themselves with saying that it is an inflammation of the membrane of the nose, which may assume an acute or chronic form, or in a short time, or very slowly, run on to ulceration.

The malady proceeds as we have already described it, but before its termination, becomes connected with farcy. Few horses die of glanders without exhibiting some appearance of farcy; and farcy in its latter stages is almost invariably accompanied by glanders; they are *different forms or stages of the same disease*.

There can be no doubt that the membrane of the nose is the original seat of glanders; that the disease is for a time purely local; that the inflammation of

the tubercles must proceed to suppuration before the matter is formed on which the poisoning of the constitution depends; that the whole circulation does at length become empoisoned; and that the horse is destroyed by the general irritation and disease produced.

Glanders may be either bred in the horse, or communicated by contagion. What we have further to remark on this malady, will be arranged under these two heads.

Improper stable management we believe to be a far more frequent cause of glanders than contagion. The air which is necessary to respiration is charged and empoisoned in its passage through the lungs, and a fresh supply is necessary for the support of life. That supply may be sufficient, barely to support life, but not to prevent the vitiated air from again and again passing to the lungs, and producing irritation and disease. The membrane of the nose, possessed of extreme sensibility for the purpose of smell, is easily irritated by this poison, and close and ill-ventilated stables oftenest witness the ravages of glanders. Professor Coleman relates a case, which proves to demonstration the rapid and fatal agency of this cause. "In the expedition to Quiberon, the horses had not been long on board the transports, before it became necessary to shut down the hatchways, (we believe for a few hours only;) the consequence of this was, that some of them were suffocated, and that all the rest were disembarked either glandered or farcied."

In a close stable, the air is not only poisoned by being repeatedly breathed, but there are other and more powerful sources of mischief. The dung and the urine are suffered to remain fermenting, and giving out injurious gases. In many dark and ill-managed stables, a portion of the dung may be swept away, but the urine lies for days at the bottom of the bed, the disgusting and putrifying nature of which is all concealed by a little fresh straw which the lazy horse keeper scatters over the top.

The stables of the gentleman are generally kept hot enough, and far too hot, although in many of them, a more rational mode of treatment is beginning to be adopted; but they are lofty and roomy, and the horses are not too much crowded together, and a most scrupulous regard is paid to cleanliness. Glanders seldom prevail there. The stables of the farmer are ill-managed and filthy enough, and the ordure and urine sometimes remain from week to week, until the horse lies on a perfect dunghill, while there is no delicacy to drain away the moisture, nor any regular pavement to prevent it from soaking into the earth, nor any water to clean even the surface, but the only instrument of purification is an old stumped broom.—Glanders seldom prevail there; for the same carelessness which permits the filth to accumulate, leaves many a cranny for the wind to enter, and sweep away the deleterious fumes from this badly roofed and uncalled place.

The stables of the horse dealer are hot enough; but a principle of strict cleanliness is enforced, for there must be nothing to offend the eye, or the nose of the customer; and there glanders are seldom found; but if the stables of many of our post-horses, and of those employed on our canals, be examined, almost too low for a tall horse to stand upright—too dark for the accumulation of filth to be perceived—too far from the eye of the master—ill-drained and ill-paved—and governed by a false principle of economy, which begrudges the labor of the man and the cleanliness and comfort of the animal; these will be the very hotbeds of the disease, and in many of these establishments it is an almost constant resident.

When speaking of the inflammation of the eye, and the effect of ill-ventilated stables in producing it, we remarked that the urine of the horse contained an unusually large quantity of hartshorn; that the litter wetted by it was disposed most rapidly to ferment, and that the gases extricated must be extremely prejudicial to so delicate an organ. It may then be easily imagined that the constant presence of those pun-

gent fumes, and the irritation which they would cause on that membrane which is the very seat of smell, must predispose for, and often generate a disease which is primarily an affection of this membrane.

Glanders may be produced by any thing that injures, or for a length of time acts upon, and weakens the vital energy of this membrane. They have been known to follow a fracture of the bones of the nose. They have been the consequence of violent catarrh, and particularly the long continued discharge from the nostrils, of which we have spoken. They have been produced by the injection of stimulating and acrid substances up the nostrils; and every thing which weakens the constitution generally, will lead to glanders. It is not only from bad stable management, but from the hardships which they endure, and the exhausted state of their constitutions, that post and machine horses are so subject to glanders; and there is scarcely an inflammatory disease to which the horse is subject, that is not occasionally wound up and terminated by the appearance of glanders.

Glanders, however, are highly contagions. The farmer cannot be too well aware of this; and considering the degree to which they often prevail, the legislature would be justified in interfering by some severe enactments, as they have done in the case of the small-pox in the human subject.

The early and marked symptom of glanders is a discharge from the nostril of a peculiar character; and if that even before it becomes prevalent, be rubbed on a wound, or on a mucus surface, as the nostrils, it will produce a similar disease. Glanders are not communicated by the air or breath. If the division between two horses were sufficiently high to prevent all smelling and snorting at each other, and contact of every kind, and they drunk not out of the same pail, a sound horse might live for years uninfected, by the side of a glandered one. The matter of glanders has been mixed up into a ball, and given to a healthy horse, without effect; yet in another experiment of the same kind, the poor animal died. The mouth or gullet had probably some small wounds or ulcers in it. Some horses have eaten the hay left by those that were glandered, and no bad consequences have followed; but others have been speedily infected. The glandorous matter must come in contact with a wound, or fall on some membrane, thin and delicate like that of the nose, and through which it may be absorbed.—It is easy then, accustomed as horses are to smell each other, and to recognise each other by the smell; eating out of the same manger, and drinking from the same pail, to imagine that the disease may be very readily communicated. One horse has passed another when he was in the act of snorting, and has become glandered. Some fillies have received the infection, from the matter blown by the wind across a lane, when a glandered horse, in the opposite field, has claimed acquaintance by neighing or snorting. It is almost impossible for an infected horse to remain long in a stable with others, without irreparable mischief.

If some persons underrate the danger, it is because the disease may remain unrecognized in the infected horse for some months or even years; and, therefore, when it appears, it is attributed to other causes, or to after inoculation. We would deeply impress it on the mind of the farmer, that no glandered horse should be employed on his farm in any kind of work, or permitted to remain for a day on his premises: nor should a glandered horse be permitted to work on any road, or even to pasture on any field. He may be capable of work for years after the disease has become undoubted, but mischief may so easily and extensively be effected, that the public interest demands that every infected animal should be summarily destroyed, or given over for experiment to a veterinary surgeon, or recognized veterinary establishment.

Our opinion of the treatment of glanders is implied in what we have just stated. There are a few instances of the spontaneous cure of chronic glanders, or glanders long established and slow in their pro-

gress. The discharge has existed for a considerable time; at length it has gradually diminished, and has ceased without medical treatment; but in the majority of these supposed cases, the matter was only pent up for a while, and then, bursting from its confinement, flowed again in double quantity; or if glanders have not reappeared, the horse, in eighteen or twenty-four months, has become farcied, or consumptive, and died. We view these cures with much suspicion; but even allowing that some have occurred, they are so few and far between, that our expressed opinion of the incurable nature of the disease, in the present state of veterinary knowledge, is scarcely affected. As for medicine, there is scarcely a drug to which a fair trial has not been given, and many of them have had a temporary reputation; but they have passed away, one after the other, and are no longer used. The blue vitriol and the Spanish fly have held out longest, and in a few cases, either nature, or these medicines, have done wonders; but, in the majority of instances, they have palpably failed. Where the life of a valuable animal is at stake, and the owner takes every precaution to prevent infection, he may subject the horse to medical treatment; but we indignantly object to the slitting of the nostril, and scraping of the cartilage, and searing of the gland, and firing the frontal and nasal bones, and to those injections of pepper and mustard, corrosive sublimate and vitriol, by which the horse has been tortured, and the practitioner disgraced. At the veterinary school, and by veterinary surgeons, it will be most desirable that every experiment should be tried to discover a remedy for this pest; but, in ordinary instances, he is not faithful to his own interest or that of his neighbors, who does not remove the possibility of danger in the most summary way.

Supposing that glanders have made their appearance in the stable of a farmer, is there any danger after he has removed or destroyed the infected horse?—certainly there is, but not to the extent that is commonly supposed. There is no necessity for pulling down the racks and mangers, or even the stable itself, as some have done. The poison resides not in the breath of the animal, but in the nasal discharge, and that can only reach certain parts of the stable; and it the mangers, and racks, and bales, and partitions, are first well scraped, and next scoured with soap and water, and then thoroughly washed with a solution of the chloride of lime, (one pint of the chloride to a pailful of water,) and the walls are lime-washed, and the head-gear burned, and the clothing baked and washed, and the pails new painted, and the iron-work exposed to a red heat, all danger will cease.

The tricks which some dealers resort to at fairs and markets, in order to conceal the existence of glanders, are most infamous, and should be visited with the severest penalty of the law. Having given the horse a brushing gallop, that he may thoroughly clear the nose, some of them blow powdered alum up the nostrils a little while before he is shown; others use white vitriol; and although the horse may be sadly tortured, about which they care nothing, the discharge is for some hours stayed. Others roll up a pledget of tow, and introduce it into the nostril, sufficiently high to escape common observation. Both these tricks may be discovered by the uneasiness of the animal, and his repeated efforts to sneeze, as well as by his general appearance, and if the disease be far advanced, most assuredly by the red or raw appearance of the nose, and by the stinking breath.

Happy should we be, if we could say any thing satisfactory of the prevention of glanders. The danger from exposure to infection can scarcely be avoided by those who travel much, and whose horses must stand in stables, the inmates of which are so promiscuous, and so frequently changed. Although we cannot prevent contagion, we have more power in preventing the disease from occurring without contagion, and that is a point of importance, at least if the opinion of Professor Coleman be correct, that not one horse in a

thousand receives the disease from contagion. To this however, we cannot subscribe, for not only the history of calvary regiments; but the experience of every breeder and proprietor of horses will prove the infectious nature of the complaint.

No fact is more certain, than that he who will keep a glandered horse in his stable, or work him in his team, will sooner or later lose the greater part of his stud. However, the generation of the disease may certainly be much prevented, and the first and most effectual mode of prevention will be to keep the stables cool and well ventilated, for the hot and poisoned air of low and confined stables is one of the most prevalent causes of glanders.

Next to ventilation stands cleanliness; for the foul air from the fermenting litter, and urine and dung, must not only be highly injurious to health generally, but irritate and predispose to inflammation that delicate membrane, which is the primary seat of the disease. If to this be added regular exercise, and occasional green meat during the summer, and carrots in the winter, we shall have stated all that can be done in the way of prevention. The farmer's horse in his cool or cold stable, and during the greater part of the year running loose when not at work, would be exempt from glanders, if at the market and fair he were not so much exposed to contagion. In truth, glanders may be considered as the consequence of the stabling of the horse. In South America and in Arabia they are unknown; but wherever the European plan of stabling has been introduced, glanders have followed in its train: and therefore if any means are resorted to for the cure of glanders, the first, and perhaps the only effectual one would be to remove every exciting cause of the disease; to restore the horse almost to a state of nature; to turn him out for a long time, or at least to throw open his stable as much as the season and the weather will permit.—Experience, however, tells us, that, although the symptoms have disappeared when the exciting causes of disease have been removed, and the horse has returned to his stable after a twelvemonth's run apparently sound, every symptom has gradually shewn itself again when these causes have been once more called into action.

(From the Genesee Farmer.)

LOSS IN FATTENING OXEN.

MESSRS. EDITORS: *Milton, March 22, 1833.*

For the benefit of others who are as ignorant of the comparative value of cattle, before and after being fatted, as I was until I had made the experiment, I am constrained to offer to you for publication this communication. My experiment was made with a yoke of large oxen, and commenced November 1st, ultima, when they were in good working condition. I will put down what I believe to have been their value at that time, \$75 00
They were fed 180 bushels potatoes, at 20c. 36 00
“ 10 “ corn, at 62½cts. 6 25
90 days at fodder and labor of feeding at 12½c. 11 25

Estimated cost, \$128 50
They weighed about 2000 lbs. for which I received 5 cts. 100 00

Making a loss of \$28 50

Although the oxen were large framed, they were not of a kind to fatten easily.

The above is not offered for publication, but with a sincere desire that it may warn others from my error.

Respectfully, W. P. W.

Note.—I am inclined to believe that farmers do not pay sufficient attention, in their selection of working oxen, to their fattening qualities. While oxen intended for the yoke command the same high price which they do at present, it seems quite important that they should possess properties fitting them for the stall as well as the yoke, in order that we may derive the greatest profit from them. W. P. W.

TURKISH HORSES.—Large apertures in the walls, and the roof constantly admitted the air, it being a principle with the Osmanleys to keep their stables cool, covering the horses with thick cloths. And, as no country presents more variety of climate than Turkey in Europe, no horses being so healthy as Turkish horses, it follows that the mode adopted with them is good—spacious, well ventilated stabling with plenty of body clothes. Horses in Turkey never stand on straw, but on the earth or sand, kept very clean and are always tethered. The practice of tethering is worthy of imitation every where; it does not distress the animal, and it prevents kicking. Nothing is more unpleasant than being between two rows of loose heels. “Extremes meet,” is exemplified in the contrary practice of the English and the Turks respecting horses the result of each being the same excellence. English stables are hot, Turkish stables are cold—English horses are high fed, Turkish horses get little else than chopped straw—it requires hours to dress an English horse; as many minutes suffice for a Turkish horse—the English snaffle would scarcely hurt a deer's mouth; the Turkish bit would break a tiger's jaw—the hoof in England is prepared to the shoe; the shoe in Turkey is fashioned to the hoof.

[*Slade's Travels.*]

MISCELLANEOUS.

(From the Genesee Farmer.)

SPRING AT BUFFALO—EMIGRATION, &c.

Thus far the spring has been uncommonly mild and forward, yet we have had very little rain. But one small shower has fallen on us for several weeks. The ice all left Lake Erie about the 24th April. May 8th, our plum and cherry trees were in full bloom. The wheat and grass in the neighborhood look well, but want more rain. The honey bees began to work about the first of April. The flowers of the willow, alder, and poplar, were then out; and I have never seen them carry in greater burdens of bread on their thighs, than during many days in April. Mine have made a large quantity of comb this spring, and considerable honey. The young bees are coming out very rapidly. There have been several young dead drones brought out of the hives. This appears to be uncommonly early for that operation. From present prospects, this promises to be an uncommonly fine bee season. Our fruit trees were never fuller of bloom, and the weather so far has been uncommonly good for them.

Never before has there been such a crowd of emigration to “the great west,” as during this spring.—It seems as though the whole eastern country was pouring out its millions for Ohio and Michigan. Ever since the 25th of April, two large steamboats have left Buffalo daily for Cleveland and Detroit; and every boat, together with all the schooners, and there are several of them which leave here every day, are literally packed down and overrun with passengers, goods, chattels, wares and merchandize; so much so, that in some instances passengers have been *pushed ashore*, to prevent the boat from being overlaid. Upwards of six hundred passengers have been taken from the wharf in one boat, this spring, at Buffalo. What a country must there be at the west; and how fertile its soil; and how mild its climate, to invite such a rush of inhabitants into its bosom! And the Dutch, too! they are beginning to come up the canal. It seems as if the whole country would be overrun with them. But they bring considerable money along, and buy out whole neighborhoods of farms. They are a queer race, however, and we might easily spare them for better folks. But so long as America seems destined to be the waste-wier, a grand receptacle of European overflow, we have little else to expect but a motley emigration.

I often think, while standing on the wharf at Buf-

falo, and looking at one of our fine large schooners, which are “up for Chicago” every week, as the crew are stowing away the bales and boxes of merchandise; and as numerous families, with cheerful and happy faces, are getting on board, with their luggage, to emigrate into those far regions; of the time, when, eight and twenty years ago, while a little boy at school, in old Massachusetts, with the American Preceptor in my hand, I used to read Andrew Ellicott's description of Niagara Falls, which it contained, (and an excellent description too it is;) and I then hoped that I should live long enough, and get rich enough, to some day or other go out into the wild wilderness and see those Falls! And I well recollect, with what thrilling interest I used to sit in my little chair by my parents, around the fire of a winter evening, and listen to tales of wonder about the “Genesees,” from those great travellers who had explored that distant country. And I well recollect, too, how all the neighborhood used to congregate about the house of a family who were “going to start” on their emigration to the “Genesee country,” or to the “Scioto.”—How their friends and relatives hung around them, and with tears and sighs of despair of ever seeing them again in this world, bid them adieu forever.—And here I am, a resident, standing on what was then almost the Ultima Thule of emigration, and witness families embark to go a thousand miles beyond us, into a new, yet partially settled country, with expectations of coming back again in three or four years at farthest, to see their friends in Maine, seven or eight hundred miles east of us; and all the way by water!

What a marvellous country do we inhabit, and what a spirit of enterprise pervades our land! Why, surely, the Americans ought to be the lappiest and most prosperous people in the world; and I truly believe they are. But to return to our emigration. I have this spring seen great numbers of good, substantial people from Ontario, Seneca, Livingston, and the central counties of Western New York, who are emigrating to the west with their families—more than I have ever known before. They say that they find no difficulty in selling their farms, and at good prices too. Does not this show a proud state of things for New York? Why are her farms sought for with such avidity? Why are lands around the lakes and canals, and in the extreme western part of the state worth, when well cleared and improved, twenty to thirty-five dollars an acre; when, even in New England, their best lands are hardly worth more? It is her immense internal improvements, and the great thoroughfares which have been opened through the rich interior, and by which she has been made the toll gate of the world, that has produced this result. Look at the immense tribute she annually receives from the other states. See the hundreds of thousands she accumulates from their travel and emigration; and what markets she thus provides for the surplus produce of our farmers. And how much is the value of her western lands increased by the cheapness of transportation on the canal! Our canal board did most wisely last winter, in lowering the price of tolls; and they will soon experience the fact, that low tolls will increase the receipts of her treasury; and that they ought to be farther reduced, down to the lowest constitutional limit; and even when at that rate, if the canal be not already choked up with boats, they ought to throw off all charges on the *tare* of goods, such as crates, boxes, casks, &c. with which they are encased, and only charge toll on the *weight of the naked article itself*. Then will our carrying trade be increased. Let the tolls be merely nominal—enough only to repair the canal and pay the interest on its debt—reduce the salt duty to six cents a bushel; afford it for the least possible price, and make three times the quantity now made—and then will be seen a state of things most gratifying: light burdens and full employment to our people. What is the paltry accumulation of a few thousands in our state treasury beyond its

most simple wants, to a vast business, and employment, and prosperity, given our citizens at large? It is of the least possible importance in comparison with their ultimate and individual prosperity.

But I am straying from my subject. I began with the spring, and have ended with a homily on canal tolls and political economy. But to return: Our season has opened upon us most auspiciously. The farmer, the mechanic, and the merchant, seem alike equally favored. May it so continue; and may heaven's choicest blessings cheer the husbandman on to his labors, and its richest bounties reward his toils.

ULMUS.

Prices Current in New York, June 8.

Beeswax, yellow, 18 a 20. Cotton, New Orleans, .12 a 15; Upland, .11 a .13; Alabama, .11 a .14. Cotton Bagging, Hemp, yd., .13 a .21; Flax, .11 a .15. Flax, American, 8 1/2 a 9. Flaxseed, 7 bush. clean, 15.00 a 15.25; rough, 13.00 a —. Flour, N. York, bbl. 5.50 a 5.62; Canal, 5.62 a 5.75; Balt. How'd st. 6.00 a —; Rh'd city mills, — a —; country, 5.62 a —; Alexand'a, 5.62 a 5.75; Fredericksburg, 5.62 a —; Petersburg, 5.62 a —; Rye flour, 3.75 a —; Indian meal, per bbl. 3.75 a —, per hhd. 16.50 a —. Grain, Wheat, North, — a —; Vir. — a —; Rye, North, .73 a .76; Corn, Yel. North, .75 a —; Barley, — a —; Oats, South and North, .38 a .44; Peas, white, dry, 7 bu. — a —; Beans, 7 bu. 8.00 a 8.50; Provisions, Beef, mess, 9.50 a 9.75; prime, 5.75 a 6.00; cargo, — a —; Pork, mess, bbl. 13.75 a 14.25, prime, 10.75 a 11.25; Lard, 7 1/2 a 9.

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals,—viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	300
Do 2 " " Do "	250
Do 1 1/2 " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each.

Half Blood and upwards.—A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenth Durham Shorthorn, very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$100.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address I. I. HITCHCOCK,
Amer. Far. Office.

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale.

Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life), is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also,—A young JACK, a son of Don Carlos, 4 years old, 43 inches high, well made, stout and promising, of same color as his sire—price \$200.

Also,—A full sister of the last, 3 years old, 44 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

I. I. HITCHCOCK,
Apr. 26—tf. Amer. Farmer Establishment.

HERBEMONT ON THE VINE AND WINE MAKING.

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States. By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents.

TWO IMPORTED MALTESE JACKS FOR SALE.

These animals were purchased in Malta in June, 1832, for two officers of the U. S. ship Concord, in which they were imported. The selection was left to one of the best judges in the island, who advertised three months previous to purchasing, for the largest and best bred Jacks, without regard to cost—more than one hundred were offered before a choice was made. They are now about three years old, and stand, one 13 1/4 and the other 13 1/2 hands high, and will yet grow three or four inches: their color is black with fawn nose, eyes and belly. In size, action and vigor, they were believed to be unsurpassed by any Jacks in Malta, and they have been pronounced by good judges, the finest ever brought into the United States. It is deemed unnecessary to say any thing about the superiority of the Malta Jacks; it being well known that they are of the high bred stock of Persia and Arabia.

These animals may be viewed and every information respecting them, may be obtained, by applying to I. I. Hitchcock, American Farmer establishment, Baltimore. The price is \$600 each.

TO BREWERS, HORSE AND CATTLE KEEPERS IN GENERAL.

For sale, a Portable Mill for bruising Malt, Oats, Beans or Corn, and a Hay or Straw Cutter.

The above Machines were imported from England, and are constructed upon the most approved plans, and are in general use by the scientific in the above lines in Great Britain. They are left for inspection with Mr. James Brown, at his Oyster Hotel and Porter Establishment, southeast corner of Paer and Pratt streets, opposite the Three Tun Tavern, Baltimore.

Mr. Brown is authorized to sell the above machinery. Price, for the Mill \$50; for the Straw Cutter \$30. June 14. 11*

HARVEST TOOLS, WHEAT FANS, &c.

SINCLAIR & MOORE, have in store, and are manufacturing a general assortment of HARVEST TOOLS, among which are

100 WHEAT FANS, double and single geared.

300 Grain CRADLES, with Seythes complete. This article is made of the best and most durable materials, and will be warranted as such.

50 doz. Grass and Grain SNEATHS.

30 do. Hay and Manure FORKS.

30 do. RAKES and Wooden tined FORKS.

SCYTHES and Sneaths, hung ready for use.

SICKLES, English and American Seythe Stones, Strickles, &c. &c.

Their Stock of CASTINGS, Agricultural Implements, Garden Tools and SEEDS, is as usual full and complete.

Also, just received from Europe, two bales, containing Lucerne and Ray Grass, Cabbage, Radish, Lettuce, and many other valuable SEEDS of last year's growth. From the appearance of this lot of Seed; and the respectability of the establishment from which they were imported, they can with the greatest confidence recommend them. May 24.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Apr. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—There is no change of consequence in the market. The wagon price of Howard street flour remains at \$5.37 1/2. The papers from the Eastern Shore speak of great damages done the crops by the long and heavy rains; but as yet this has had no effect on the market.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 5.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 394 hhd. Md.; 117 hhd. Ohio; 4 hhd. Penn. and 1 hhd. Ken.—total 516 hhd.

FLOUR—best white wheat family \$6 75 a 7.25; super Howard-street, 5.56 1/2 a 5.62 1/2; city mills, 5.75 a —; city mills extra 6.00 a —; CORN MEAL bbl 5 62 1/2; GRAIN, best red wheat, 1.12 a 1.18; white do 1.22 a 1.25; —CORN, white, 64 a 65, yellow, 65 a 66; —RYE, 68 a 70 —OATS, 37 1/2 a 41.—BEANS, 75 a 80.—PEAS, 65 a 70 —CLOVER-SEED 8.00 a —TIMOTHY, — a —ORCHARD GRASS 3.00 a —Tall Meadow Oat Grass 2.00 a 2.50—Herd's, — a —Lucerne — a 3 1/2 lb.—BARLEY,—FALSFEE 1.50 a 1.62—COTTON Va. 11 1/2 a 13—Lou. 12 1/2 a 14—Alab. 11 1/2 a 13—Tenn. 11 a 12 1/2; N. Car. 12 a 13; Upland 12 1/2 a 13 1/2—WHISKY, hhd. 1st p. 28 1/2 a; —in bbls. 31 a 32—Wool, Washed, Prime or Saxony Fleece 45 a 50; American Full Blood, 38 a 42; three quarters do. 33 a 38; half do. 30 a 33; quarter do. 28 a 30; common 25 a 28. Unwashed, Prime or Saxony Fleece, 25 a 30; American Full Blood, 22 a 25; three quarters do. 20 a 22; half do. 18 a 20; quarter do 16 a 18; common, 16 a 18 Hvar, Russia, ton, \$195 a 205. Iron, gray pig for foundries per ton 33.00 a —; high pig for forges, per ton, 28.40 a 30.00; bar Sus. per ton, 75.00 a 85.00.—Prime Beef on the hoof, 5.75 a 6.50—Oak wood, 3.00 a 3.25; Hickory, 4.00 a 4.50; Pine, 2.00.

CONTENTS OF THIS NUMBER.

Editorial; Exhibition of the Horticultural Society; Letter from Anthony Morris stating the Cause of the Failure of the Fellenberg School at Bolton Farm; Advantages of a general Agricultural Agency—Soap Ley in Gardens—Prize Essay—Depth of Rain for May—Chick in the Egg—Foreign Markets—On the Culture of Wheat in the New England States—Culture of Flax on the Plan pursued in Ireland—On Setting Wheat—Permanent Pastures best for Grazing—Cutting off Indian Corn in the Fall—On Forcing Bulbs to cause them to Flower in Winter—Notice of some Vernal Flowers—Chestnut Timber—On Glanders in Horses; Symptoms by which it can be recognised; Contagious; Clean and Well Ventilated Stables best security against—Loss in Fattening Oxen—Spring at Buffalo, New York; Emigration, &c.—Prices Current of Country Produce in the New York and Baltimore Markets—Advertisements.

The American Farmer,

Edited by GIDEON B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum: due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect AT THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

5. DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "J. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, JUNE 21, 1833.

HORTICULTURAL ADDRESS.—We are much indebted to the Committee of Arrangement for a copy of Mr. Kennedy's Address to the Horticultural Society at its late celebration. Our opinion of this production was freely stated in our last, and we need not now repeat it; but we cannot avoid requesting the reader's attention to it, being satisfied that no one can rise from its perusal without being edified by it.

AMERICAN NANKEN.—We have before us a beautiful specimen of American nankeen, made from nankeen colored cotton, raised by Mr. Forsythe of Georgia. The nankeen cotton was first raised in the south, eight or ten years ago, but was not then thought much of—as is the case with all new articles, it was with difficulty that persons could be found to try it. Mr. Forsythe has persevered until he has been able to induce the manufacturers to work up the raw material, and thus bring the article fairly into the market. The specimen before us, a piece of seven yards, is really beautiful; somewhat darker colored than the Indian article, and much superior to the miserable imitations from the English looms and dye shops. It being of the natural color of the cotton, it does not fade by wear and washing; and we are informed that Mr. Forsythe thinks the strongest mineral acids will not extract the color. This may be correct, but all vegetable colors disappear under the action of chlorine—and we shall take an early opportunity to test the fastness of the color of this article by the use of the chlorine, and other chemical agents. Mr. Nathaniel F. Williams, merchant of this city, agent for the sale of the nankeen, to whom we are indebted for an opportunity of examining it, informs us that a friend of his had accidentally got a large spot of ink on a new pair of pantaloons, which he considered had spoiled them. Mr. W. advised him to apply a little lemon juice and salt to the spot, and expose it to the sun, which was done, the ink extracted, and the color of the cloth remained unchanged.

We have thought it important to the interests of the southern cotton planters, that a knowledge of the value of this nankeen cotton should be disseminated, as the manufacture of nankeen will add to the consumption of the raw material. No one will ever wear the imitated article when they can get the genuine one. The color of the common imported nankeen disappears on the first washing, and clothes made of it are, therefore, very soon laid aside. We recommend a trial of this nankeen, and also the culture of the cotton, as an important object of attention to our southern friends.

SUN-FLOWER OIL.—This article is beginning to attract attention in the west. Messrs. Prouty & Co. of Whartons, Ohio, in a letter to the editor of the American Farmer, state that they are now engaged in the manufacture of sun-flower oil, and that they could forward to Baltimore eight or ten barrels immediately, if there was a prospect of its meeting a ready sale. Sun flower oil is used in York, Pa. in paints, in lamps and as a substitute for olive oil on the table. We use it, and prefer it on all occasions instead of olive oil. We would recommend a fair trial of it by the painters, and hope the manufacturers will not be discouraged by the want of a market.

THE GREAT GRAPEVINE.—The Newbern Spectator makes the following remark, on publishing the certificate of the number of bunches on Mr. Willis' Grapevine. The quotation from *Irenæus* is doubtless intended to ridicule the statement relative to the produce of Mr. W's vine, which the respectability of that gentleman renders gratuitous.

"Since reading the above, we are by no means so

incredulous respecting the vines described by Irenæus, Papias, and others, which are to gladden the hearts of those whose happy lot it shall be to witness the Millennium.

"The days shall come," says Irenæus, "in which there shall be vines which shall severally have ten thousand branches, and every of these branches shall have ten thousand lesser branches, and every of these lesser branches shall have ten thousand twigs, and every one of these twigs shall have ten thousand clusters of grapes, and in every of these clusters there shall be ten thousand grapes, and every one of these grapes being pressed shall yield two hundred and seventy-five gallons of wine; and when one shall take hold of one of these bunches, another bunch shall cry out: 'I am a better bunch, take me!'"

"Mr Willis may learn from this that there is yet room for improvement in the cultivation of this care-subduing fruit."

HORTICULTURAL SOCIETY.

At the general meeting of the Society, on Wednesday last, the following report of the committee on premiums was made.

The committee appointed by the Horticultural Society of Maryland to award the premiums offered at the first exhibition, beg leave respectfully to submit the following report:—

They congratulate the society that the duties of the committee of arrangements have been so ably fulfilled, and have been so successful as to have presented in this first exhibition of the Society, a display of fruits, flowers and plants, which not the most sanguine could have anticipated from the present limited means and resources of the Society. The benefits to be derived from the association have hence, at once been acknowledged, and the universal expression of approbation on the part of the community at this exhibition, has given a surety that every subsequent effort will be fostered and sustained. The committee have been fully sensible of the responsibility under which they have acted in coming to a decision in awarding the premiums on this occasion, a responsibility which will be considerably lightened on future occasions by particularizing the objects for which premiums will be given. Whilst they feel satisfied at the awards they have made, they regret that it has not been in their power to include other objects presented, which have received deservedly the commendation of visitors—nor has it been in the power of the committee, in the limited time which has been allotted to them by the society, to make particular mention of these objects—a full report of which will be hereafter prepared. In acknowledging the great deficiency in the quantity of vegetables exhibited, they have every reason to attribute this circumstance to the shortness of the time which has elapsed since the organization of the society and its present exhibition, a period which has not enabled the gardeners of our state generally to prepare fit objects. This will be obviated at the next exhibition, the premiums for which will be offered in the course of the present month.

The committee adjudge:

Premium, No. 1—A silver Cream Jug—value \$20—to Mr. Sam'l Feast, for raspberries, grown by him from seed. The fruit is of the most delicate kind, large, and of fine flavor. For the choice collection of exotics exhibited by this gentleman, the thanks of the Society are due. The heaths, especially, deserve notice, evidencing by their good appearance, the care and attention bestowed on their culture.

Premium, No. 2—A silver Goblet—value \$15—to Mr. John Feast, for his choice collection of *Pelargoniums*, and other exotics exhibited. To this gentleman in no less a degree are the thanks of the Society due for the rare and beautiful collection of plants exhibited, and for the care and attention bestowed on the culture of plants generally.

Premium, No. 3—Silver cup—value \$10—Mr.

Joshua Peirce of Washington, for his choice collection of lemons, oranges, citrons, limes. This collection attracted, and was justly entitled to much admiration.

Premium, No. 4—Silver cup—value \$10, to John B. Bastian, for a fine specimen of Montmorency cherry, and other fruits, and for a number of fine exotics.

Premium, No. 5—Silver Cup—value \$10, to Emory Genous, gardener at Druid Hill, seat of Lloyd N. Rogers, Esq. for three baskets of fruit, strawberries, raspberries and cherries—the strawberries, especially, were of the largest and best kind.

Premium, No. 6—Silver Cup—value \$10, to Thos. Dorsey, for the best specimen of vegetables.

Premium, No. 7—Silver Cup—value \$10, to Mrs. Isaac McKim, for the best gooseberries.

Premium No. 8—Silver Medal, value \$5, to Mrs. T. L. Emory, for a beautiful collection of Exotics.

Premium No. 9—Silver Medal value \$5, to Mrs. Edmondson, for a large basket of fine Oranges and Lemons, and a great variety of rare Exotics.

Premium No. 10—Silver Medal, value \$5, to Robert Sinclair, for a specimen of large Gooseberries, and various vegetables. The fruit varied in size with those which received Premium No. 7.

Signed, B. J. CHEN, Chairman.
HENRY SCHROEDER,
THOMAS EDMONDSON, Jr.
ZEBULON WATERS,
EDWARD KURTZ,
WM. G. THOMAS.

The list of premiums to be offered for specific objects during the ensuing year, will be published in the course of the month. The committees of the Council on fruit and vegetables will meet every Saturday morning between the hours of 8 and 9 at the Farmer Office, in order to receive and examine such objects as may be presented to them for their respective departments. It is to be understood that the premiums about to be offered in these two departments will be adjudged by the reports of these Committees.

By order of the Council,
H. F. DICKENET, Sec'y.

(From the Genesee Farmer.)

PRESERVING BEES IN WINTER.

MR. TUCKER: Bergen, Genesee, Co. May, 17, 1833.

I have seen several articles on the subject of bees in your valuable paper, the Genesee Farmer, and being a subscriber, I wish to give to the public the fruits of my experience. I have kept bees for fifteen years. Last spring a friend of mine told me if I would bury my bees in the ground I could keep them through the winter in that manner; accordingly I buried two hives that had but very little honey. I was confident that they would not winter for the want of food; I therefore thought I would try the experiment. I took them from the ground the 18th day of April, and found them in good health. They had not made use of the honey, as there appeared to be as much honey in the spring as when I put them in the ground. They must be buried below the frost, and in such manner as to prevent the air from coming to them.

H. D. GIFFORD.

On this subject, we find the following paragraph in the newspapers—where it originated we know not:

Preserving Bees in Winter.—Mr. Etheridge, of Montrose, Penn., who keeps a considerable quantity of bees, buried seven hives in the ground last fall by placing them on the ground, covering them first with straw, and then burying them in the earth to the depth of about ten inches. About the first of this month he took them out, and found them to be in excellent condition. Some of the hives when buried were poorly provided with honey, and Mr. E. is of opinion that they could not have been preserved through the winter in the ordinary way.

AGRICULTURE.

(From the Southern Agriculturist.)

ACCOUNT OF AN AGRICULTURAL EXCURSION.

Made into the South of Georgia, in the winter of 1852.

BY THE EDITOR.

(Continued from page 75.)

From "St. Simon's" we again visited "Hopeton," touching on our way at "Butler's" and "Champney's Island," both of which are of considerable size, especially the latter. The crops cultivated are rice, sugar-cane and cotton; the first is principally attended to, the two last being only in small quantities, so as to alternate a portion of the fields, and also to ensure some return for the labor expended on the plantation which is best secured by a variety of crops, especially where they are all valuable. Most of the river plantations near Darien are better calculated for the culture of rice than any other crop, especially the islands, yet a rotation is generally adopted, and by many is thought necessary to ensure a full crop of rice. A distinguished planter of that place gave it as his opinion, based on the experience of many years, that in the course of ten years nothing was lost, by introducing a crop of cotton every third year, even were the cotton to prove wholly unproductive, for the increase in the rice crop would fully compensate for the lost year, so that at the expiration of ten years, the product obtained of rice, would be equal to what it would have been, had the fields been kept solely under this culture. The cotton crops, therefore, are considered as clear gain. The rice-planters of South Carolina have not, we believe, introduced any other crop on their fields, owing to the greater value of this over any other which they could cultivate; but, if in the course of years, the product remain the same, although every third or fourth year is devoted to another, it would be worthy of trial whether a rotation of crops might not be advantageously adopted. An experiment of this kind might be made on a small field, or a square be devoted to this purpose. This alternation of crops, however, is not considered *by all* to be necessary to the successful culture of rice. Some believe that it can be done without, and others adopt it as a convenience.

Col. J. F. Green is of opinion that it is not necessary, he observes:—"There can be no doubt but an alternation of crops where it can be practised conveniently is highly judicious; but I do not think it at all necessary to ensure a good rice crop, if fortunately situated between the two extremes of salt and freshets. From the approximation we can make between harvesting and planting in placing the land nearly in the condition we should find it, after raising cotton, cane, or any thing else that required to be kept dry through the entire season, by having the fields properly ditched and ploughed, and kept dry from harvesting to planting. These are two necessary precautions that are little observed in this neighborhood, more particularly, perhaps, that of ploughing."

A few of the planters have of late years planted entire crops of rice, on account of the uncertainty of realizing a full crop of cotton from low lands. Some have substituted cane in lieu of cotton; but we did not find the culture of this plant extending. In fact, several planters were about abandoning it, in consequence of its requiring more labor in planting, harvesting and preparing it for market. Also the additional expense necessary to erect an efficient mill for grinding the cane, and building sugar-houses, &c. A majority of the rice planters, we understand, who cultivate the cane, prefer making syrup to manufacturing sugar, believing it to be more profitable, owing to the want of season to mature the cane, and the inefficient machinery for grinding the cane.

Some of the planters with whom we conversed, were of an opinion, that the cane crop on low land

was not as valuable as the rice crop, the product being small and the quality inferior. Mr. J. H. Couper has proved it to be otherwise, and both cane and cotton enter into a regular rotation on his fields.

The mode of cultivating rice in this neighborhood will be best understood by giving the practice of one or two of the planters. We will here give that of Col. Green, who cultivates an island immediately opposite to Darien, from which it is separated by one of the branches of the Altamaha river. These notes were furnished us by Col. Green, merely for reference, but as we cannot improve the account which he has himself given, we prefer making use of them as they are, rather than, by altering, lose any part.

"The island on which I plant is known as 'General's Island,' and contains about eight hundred acres of tide land. I have now under cultivation about two hundred and twenty acres. My negroes are settled on the main, from an impression that a low damp situation was not as congenial to health as a higher and drier site; and where better water could be procured for us, and, also, that there would be nothing risked by gales which do at times not only sweep off entire crops, but a large portion of the negroes. There is some risk to be run in daily crossing the river, and occasionally much exposure to rain; but of the two hazards, I prefer the latter.

"I prepare my land by having large and tight banks and tight trunks, and as soon as possible thoroughly drain, putting my drains parallel with each other, at fifty feet apart, from fourteen to eighteen inches wide, and not less than three feet deep. The inequality of the surface is generally so great that a drain shallower than that, will not dry the lower spots sufficiently. I think it important also, that the ditches and drains should be perfectly straight, and all stumps and roots perfectly removed so as to present no point on which floating trash may hang, otherwise barriers will soon be formed. When my fields are dried for harvesting, they are generally kept dry until again planted; the stubble will die with less cold, and more effectually when kept dry, than if suffered to be kept wet or even damp. As soon as the stubble will burn, fire is applied to it, and burnt as perfectly as possible; the earlier it is burnt the more numerous the birds are likely to collect on the fields, and in many instances the ducks also; and pick up what scattered rice may then be left on the surface, as it is perfectly exposed. I think it best to prohibit the pasturage of the fields to all horned cattle and horses. Rice-field butter is certainly very fine, but it is purchased at an extravagant price. The plough is introduced when the roots are sufficiently decayed to admit its use, (the Freeborn or Dagon plough I find best,) and the land is as perfectly turned as possible three or four inches deep; by which process, the rice which has escaped the birds is so late in getting up that it rarely ever overtakes the crop, and your crop invariably comes up free from grass. Some short time previous to planting, a heavy harrow with good iron teeth is passed over the ploughed land once or twice, until it is reduced sufficiently fine for trenching. I frequently use the trenching plough, but prefer the hoe, as it is neater in its execution; but the plough despatches work rapidly where you open three rows at once. I prefer my trenches shallow and not exceeding five inches wide, and about fourteen inches from centre to centre. In land thus prepared two bushels of seed is quite enough to the acre; in land not broken up by the hoe or plough, or on new land that is rough it requires to be planted thicker, say two and a half to three bushels per acre. I then flow from three to seven days, at first as deep as I can, to float the trash which should be taken off as quick and as clean as possible, the water is then reduced down so as to protect the higher spots of the field from the birds. The field is dried as soon as the rice is perceived to have sprouted pretty well, which never exceeds seven days, unless the weather proves very cold, but in no one case ought it to be kept flowed

deep long. I have seen whole fields of rice entirely rotted by deep flowing. This flow serves the double purpose of cleaning the field of small roots that may have been ploughed up, or particles of stubble or grass that have escaped the fire, and destroying insects that prove sometimes very destructive to a young crop. I disapprove of the point flow, except under peculiar circumstances: if the birds are very troublesome, and the land very level, the rice may be protected a few days from the birds, in the point. If the land should be unlevel, I think that more is sacrificed by this flow than would be lost by the birds. On the poor black soil that is frequently found on the main, adjoining the highlands, and which is invariably level, and from its peculiar soil, is very difficult to dry when once saturated, I would always advise the point-flow, and to be continued on from twenty-five to thirty days, the rice by that time attains considerable size, and most generally the field is perfectly clear of grass. The rice on this quality of land is less likely to become diseased by fox, rust, or spot, under this mode of treatment, than giving what is termed, the long flow, at the usual time. It will then require to be kept dry and hoed until it has formed the ear.

"But to return, as soon as I am done planting and the rice is up, I commence hoeing—at that period the work is light—the rice is so small that it must necessarily be hoed shallow, and there is no grass, and generally but few weeds to pick out of it, at that early season. Every tolerable good land is able to hoe a half acre with ease. I prefer to hoe twice before I flow, if I have time. This depends also much on the tides, as lands that are not old and much worn cannot be flowed generally but on spring tides. This is known as the long flow, and the use of it requires as much or more discretion in the planter than any other point in the cultivation of the crop. When the water may be changed in eight or ten days, and the atmosphere is moist and calm, it will flourish for thirty days; but if on the other hand, the weather should be dry and cool, and the tides too low to allow a change of water on the fields, I have seen the plant show indications of disease in ten days. I would recommend, under such circumstances, to dry the field and hoe deep and thoroughly as soon as the land is sufficiently dry. The object is to keep the plant in as healthy and growing condition as possible. Hence it becomes necessary to change the process of culture with it—if disease appears while it is dry, flow, or if when flowed, dry.

"As a general rule, the long-flow is kept on from fifteen to twenty days. I prefer flowing shallow unless the fields had not been properly cleared of trash in the previous flow, or it should have become much infested with weeds previous to hoeing; in such a case the water should be put on deep to float the trash or weeds, but under no circumstances ought it to be suffered to remain under this deep flow beyond three or four days. Whilst the rice is under this flow, it is advisable to have the higher spots in the field hoed and picked clean of grass. The first hoeing after this flow should be given as soon as the land is sufficiently dry, which, if properly drained, will not require more than a week, and be hoed deep, not less than two or three inches, and the surface well broken—care should now be taken that all the grass be perfectly removed. One-third of an acre is a pretty fair average for a hand per day to hoe at this time. If time admits, the crop should all be hoed over again, but hoed shallow, and what grass escaped at the previous working must now be removed; this is termed the 'lay-by hoeing,' and is light labor—a half to three quarters of an acre per hand per day. The crop is now supposed to be made, and requires nothing more but to be flowed and the water changed as convenient. The interval between the two last flowings is generally about six weeks, and by the time the rice has received this last flow, it has formed two, and if well grown, three joints. This flow should not be deeper than the long flow, until the rice ears

out, it is then advisable to flow deep to support the plant and keep it from lodging or falling. Seven acres of rice may be cultivated to the hand, if on a good pitch of tide, when once properly ditched with the assistance of ploughs and harrows to aid in preparing it for planting, or five acres of rice and two acres of provision, and unless the proportion of potatoes should be very small, I would prefer the seven acres of rice as the lighter labor.

"The crop of rice, as an average crop for the entire rice-growing-country, is greater than in South Carolina per acre, from the comparatively large amount of new land, and the system of alternating the fields; but the amount planted per hand is small compared with the usual amount planted in South Carolina; it does not exceed four acres, and in many instances, is much below it. The mode of planting and culture also differs widely from that pursued in South Carolina; the rows are wider apart, say eighteen inches from centre to centre, and I believe never exceeding one and a half bushels of rice, planted to the acre, and I believe five pecks per acre is about the medium. Very little water is used in cultivating the crop previous to its jointing, and never, as far as I am aware of, used as an agent to destroy the grass; this renders it necessary to hoe oftener, and adds to the labor of keeping the crop clean; and I believe deteriorates the quality of the rice. I would estimate the average rice crop of this neighborhood at fifty bushels per acre. I am perfectly aware that many persons will doubt this as being too low an estimate; be it so, I will then, to convey my idea, say it is twenty per cent. greater than is made usually as an average crop on Sam-Pit, Black River, Pee Dee, or Waccamaw. I know the proneness in planters and overseers to over estimate the real amount of their crops. I do not think that more than forty bushels per acre is made on an average on those rivers. Here and there a solitary planter makes sixty bushels per acre, or occasionally a solitary field may make it; but that would not be a fair estimate of the average crop of the district for a succession of years."

The management of this crop on "Butlers' Island," has already been given in Vol. i. p. 409 of this Journal, and we refer our readers to it for further information. In our account of "Hopeton," we will give the mode of culture pursued by Mr. J. H. Couper, which with what we have already given will convey a tolerably correct idea of that pursued by the planters generally in this section of country. Although there are many islands in this river, and the borders are swampy, yet, there is, comparatively, but a small portion which is well adapted to the culture of rice. The right pitch of tide does not extend more than three miles, commencing at "Hopeton," and terminating with "Champney's Island," above the former the crops would be extremely uncertain from the liability to injury from freshets, and below "Champney's Island," the salt water would occasionally prove an unwelcome visitor. But even the whole of the space between these two points is not occupied, and there is much fine land yet to be brought under culture. The river here is very wide and divided into several large branches. Most of the islands are still in a state of nature, thickly wooded, and apparently of great fertility; but they are all more or less liable to be overflowed by freshets, for although the river has numerous large branches and several out-lets, yet owing to its great length, and the tributary streams which flow into it, freshets are not uncommon, and are sometimes very destructive.

A peculiarity we noticed here, and which is common in this state, is to regulate all the operations of the rice crop by the spring tides. All of their work is done in reference to these, whether it be planting or hoeing, for it is only at these periods that they can flow their fields; consequently, if they are not prepared, they must wait for the next. They, therefore, endeavor to have certain portions of their work completed by that time—certain fields planted, cer-

tain fields hoed, &c. There is not (owing to this cause) all the precision which is to be found on the Carolina plantations, nor can science be as effectually brought to aid the planter; for whilst with the Carolina planter, each operation is governed by the particular state of the crop, and water is put on or run off as may be required, the crop hoed, and kept dry, or flowed, as may be thought most conducive to its health, the Georgia planter is obliged to wait certain periodical flowings of the tides, which must operate against him in some degree, although, he can regulate his work to meet them in most cases, as these intervals are short. The average product of rice per acre on this river is greater than in Carolina, owing to the causes stated by Col. Green. We heard of several instances of four barrels being made to the acre.

(To be continued.)

(From the Virginia Farmer.)

AGRICULTURE IN VIRGINIA.

As it is the duty of every friend of agriculture to write in the advancement of this noble, yet neglected subject, I have determined to respond to your inquiry with regard to its decline in our state, and as to the means by which we may hope it will be improved.

Our injudicious system of husbandry, and its inevitable consequence, the excessive impoverishment of our soil, obvious and universal as they unquestionably are, may be attributed to various causes;—None of them, however, either in their origin or effect, beyond the control of that intelligence and perseverance, which are essential to success in all the various pursuits allotted to man. In ascertaining the defects of our present mode of cultivation, it may be well to examine the sources from which they have sprung. Most of them have been bequeathed to us, with our paternal inheritance; and whilst we have enjoyed the latter, we have but too generally adhered to the former. Among the most prominent allurements to an exhausting system of cultivation presented to our ancestors, may be esteemed the very great facilities afforded them, of procuring sustenance. The slight and alluvial soil found on the margin of our water courses, producing almost spontaneously abundant crops of corn and wheat, aided by the fish and fowl of those streams, removed all incentives to the energy and attention of the practical farmer. Another cause of almost total inattention to the preservation of the soil, was the strong inducement offered by the certainty of procuring another subject on which to work, by means of new clearings. Land being very cheap, the farmer who had exhausted his fields by unremitted tillage, and unlimited pasturage, found, in a resort to the *virgin mold*, a method of remedying the defects introduced by his former bad cultivation, at once expeditious and congenial to his taste. Thus thousands of acres, which by judicious management, might have been preserved as fruitful as in their original state, were rendered barren. The frequent incursions also, of those hostile tribes by whom the first settlers of our country were surrounded, presented no inconsiderable obstacle to a uniform system of farming, as the reward of labor was thereby rendered uncertain, and the regular employments of the yeomen of our country, were frequently interrupted by the call to arms. Another cause most adverse to agricultural improvement, is the extensive culture of tobacco. To this, perhaps more than any thing else, may be ascribed the rapid impoverishment of the eastern and southern sections of our state.—Those best acquainted with this crop, will be most able to appreciate the correctness of this assertion, as the experience of each year must render them more aware, of the continued destruction of forest land, the monopoly of all the manure on the farm, and the exclusive attention and extravagant quantity of labor bestowed on this crop.

To the fact of the far greater proportion of the landed property of our state being held by comparatively few persons, may likewise be attributed many

of the agricultural errors prevalent among us. The result of this distribution of land was, that the possessors of these estates, unmanageable from their great size, paid but little personal attention to them, depending generally on mercenary agents, who felt no interest in the improvement or even preservation of the soil, and whose sole object was to obtain the utmost degree of production from the estate, during the period of their occupancy, seldom bestowing a thought on its future condition, when the time should arrive for them to be superseded by others of the same class, who, by bringing a still larger portion of land under this wretched system of cultivation, sought at once the making their own fortunes, and satisfying the demands of the proprietor. Last, though not least, of all the evils with which our state has had to contend, in an agricultural, no less than a political point of view, has been our laboring population. To procure the requisite quantity of effective force, we maintain a considerable proportion of those who are totally useless, either from age or other circumstances, and the most valuable acquire for their support, a very considerable supply of those articles of consumption,—for example, corn and bacon; which, in their production, operate most injuriously on our lands.

Having thus investigated some of the causes, which most certainly and manifestly impaired the fertility of our country, let us now look to the means by which we may hope to effect a change in the aspect of our affairs. First, I should say, that improvement must be an object of primary importance; that system of cultivation is radically defective, which does not tend unvaryingly to this object. We may lay it down as a rule, universal in its application, that if our lands are not improving, they are declining; and we are constantly either increasing our real capital, by the enhanced value of our soil, or lessening it by the deterioration thereof. A small degree of observation and reflection, must convince every man of this.

Agricultural improvement has already commenced, and, we may reasonably hope, that its progress will be more rapid each succeeding year. Of all the causes, to which this may be ascribed, one of the most obvious, is the gradual division of property among those who feel a personal interest in it,—expecting to derive from it support for themselves and their families, and who will therefore bestow upon it that attention which will reasonably ensure success. Much of that talent and energy which have hitherto been exclusively devoted to literary professions, will be employed in ascertaining why disappointments in agriculture so frequently occur? The sources of these will be discovered, and the remedy applied. Analogy and experience both sustain this opinion. In the operation of nature, no less than in those of the mechanical arts, effects flow from causes, the connection may not be so apparent, but it is as inseparable. A substitution of ameliorating crops, combined with such a distribution of manure, as will benefit our lands generally, will be attended with the best effect.

From the application of science to agriculture, we may entertain the most lively hopes. Need I do more in confirmation of this opinion, than refer to the unprecedented improvement which has been produced in the eastern part of our country by the use of marle; and in the middle and western, by gypsum and clover, crops have been doubled, and the fertility of the soil, instead of being increased in a proportion at least equal to that of its production. As another illustration of this principle, I would mention the fact of the smut being completely arrested in its progress; an evil which at one period threatened the wheat growing sections of our state with the most disastrous results. It is needless to multiply examples.—The day is not far distant when conviction will supersede skepticism, and we shall exhibit in our exorbitant crops and verdant fields, husbandry, worthy of the Old Dominion. Such, at least, is the hope of

A FRIEND TO AGRICULTURE.

HORTICULTURE.

ADDRESS

Delivered before the HORTICULTURAL SOCIETY OF MARYLAND, at its First Annual Exhibition, June 12, 1833,—BY JOHN P. KENNEDY.

Ladies and Gentlemen of the Horticultural Society:

I hold it an undeserved favor that you have selected me to make the address on the occasion of the present celebration. Though not wanting in a just estimate of the worth of the objects of this society, nor of the efficiency of the means in your power to accomplish them,—nay, not less imbued, I trust, than any of you, with a lively hope to see the institution which you have lately organized fulfil its destined purpose, and shed its manifold beneficent influences upon our community, yet I cannot but feel that there are many gentlemen amongst you, whose active zeal in this enterprise, whose peculiar study of the pursuits to which it is allied, whose intelligence, taste and scholarship might have directed your regards to them, much more appropriately than to myself, when you were about to appoint an individual to recommend in public discourse the excellent aims for which you have associated. In allotting this duty to me, therefore, I must be permitted to esteem it a personal token of your consideration, for which I am bound to make you a grateful acknowledgment; and I desire to add to this expression of my thanks, the avowal that the task you have set before me is one which I take an especial pleasure in performing. I approach it with a cheerful resolution, because, in the first place, I feel assured that the same friendly concern which impelled you to put this duty upon me, will indulgently overlook the necessary imperfections of my performance; and, in the second place, because the subject itself is full of agreeable appliances and pleasant topics. I address you in the midst of a wilderness of sweets, where the eye has been delighted with the most exquisite of nature's forms and colors, developed in her choicest flowers, and where the air is redolent with the odor of a thousand perfumes: the treasures of the neighboring gardens have been spread around you in a splendid array of rare and luxuriant productions: this hall has been transmutated into a charmed grove, where one might fancy some unearthly enchanter had wrought his spell to delight the senses with all the riches of shape, hue and fragrance:

"Ten thousand colors wafted through the air,
In magic glances play upon the eye,
Combining in their endless fairy forms
A wild creation."

Around you, participating in this banquet of delights, are gathered your friends and neighbors, all joyous as yourselves, giving and receiving the quick impulse of pleasure engendered by the scene, and, by the sympathy of mutual satisfactions, quickening, enlarging and renewing the cheerfulness of this festival. Here, as if in rivalry with the delicate perfections of this congregation of plant and flower, are grouped about us the not less brilliant assemblage of our fair townswomen, of whom it is no flattery to say that their far-renowned beauty is the least of their attractions. Their presence here is an auspicious omen for the success of your undertaking. Where they delight to come, we may assure ourselves that the graceful genius of their sex will infuse into the labors and observances of the place the predominating flavor of their own sensitive and refined taste. This hall of flowers should be peculiarly their temple; and we would fain hope that at each return of this celebration we may find the pursuits and labors of the society applauded, promoted and sustained by the increasing zeal with which the ladies of Baltimore devote themselves to its prosperity. Then, too, the season of the year at which we meet lends no small share of allurements to the festivity of this ceremony. Spring has just fallen into the arms of summer: the freshest green is on

the fields, the deepest shade is in the grove: the balmy air breathes of rural enjoyment: fruits and flowers are found united in the gardens; and all that spring can furnish of the beautiful is mingled with much that summer can supply of the delicious. The physical frame of man is yet unexhausted by prolonged heats; the timely and frequent shower yet refreshes the face of earth, and no parching drought at this season deforms the landscape: Vertumnus has successively discarded his various disguises, and has won the prodigal Pomona, and Flora is close in the train of the wedded pair. This may, therefore, be emphatically called the season of delight and beauty.

From all these causes, I may truly say my theme is full of agreeable topics, and that to descend on them, as is my province, is more of a recreation than a task. Would that I were able adequately to express the emotions which the contemplation of these subjects raises in my mind!—that I were able to excite in your breasts the keen sense of enjoyment with which my own is moved in the discharge of the duty to which your kindness has called me!

This is the first public exhibition of the society. It is an experiment upon the taste and feeling of this community; and from the general and favorable interest which the endeavor has won, I think it can scarcely be deemed an experiment of doubtful success. If the event be prosperous, it will furnish a gratifying evidence that the citizens of our state have arrived at a wholesome elevation of moral and intellectual refinement.

Every stage of society, in the progress of man from rude and unpolished life up to the extreme of civilization, is distinguished by its appropriate character. In the first or earlier eras, we may see him struggling, with unassisted strength, for the mere rough materials of subsistence: a little more advanced, we shall find him diligent and inventive to enlarge the number of his comforts: still further on his career, his history will present him in search of superfluities;—the elegancies of life will then engage his pursuit, and he will be assiduous to accumulate what may adorn and illustrate his condition: passing forward beyond this stage, his high-fed desires and stimulated passions scorn the wholesome aliment that previously made him happy, and he will covet far-sought enjoyments; his taste rendered vicious by satiety, difficult to please, adulterated and sickly, will only be content with the gratifications which are to be procured at the greatest cost, and with the largest and most perilous expenditure of labor. Such, in brief, is the march of humanity;—and thus do the wants of that restless, changeable creature man provoke him to pursuits and attainments which severally give a sign or character to the manifold varieties of human society, from the day of the untrilled savage, to that of the frivolous and effete voluptuary.

I need not say, that the middle degrees on this scale are the most healthful and the most happy:—they unite the hardihood and endeavor of primitive society with the refinement of the elder changes—alike removed from the vices of both.

It is worth observation that in the infancy of social existence man works alone. He works at odds and disadvantage with his adversary want: his young invention has not yet supplied him with implements: a bare right arm, braced by toil and brawn by use, is the weapon with which he goes forth to do battle with hunger. The skin of the conquered Neimian lion is the only garment of this Hercules; and with no other assistance than that of his club he destroys the wild boar of Erymanthus, and drags up the triple headed Cerberus to the light of the sun. His is the victory achieved by brute force, and with many an agonizing strain of the muscles; and when he prostrates his giant enemy and sets his foot upon his breast, he dashes the drops from his brow, as one who has gained the day in a mortal encounter. It is not long, however, before he finds that his fellow man may be made an efficient instrument in this war with neces-

sity: that a combination will avail more than separate and unconcerted struggles;—and with this aim he subdues his brother and enlists him as a co-laborer. Then he discovers further, that working with associated mind, as well as with united strength, increases his power an hundred fold. This important secret of association is no sooner carried into use than the whole surface of human existence changes: improvement rapidly follows on the steps of improvement; useful things abound; comforts, luxuries, elegancies spring up like magical creations: life moves upon multiplied springs and wheels: the work of hands grows to be insignificant, when set beside the work of minds that have seized upon the great engine of nature. Wind, and water, and fire, and vapor are brought into tremendous alliance;—and man, the dwarf, becomes an irresistible giant, and smiles at the marvellous speed and overwhelming impetus with which his omnipotent machinery produces whatsoever his genius directs.

The same sense and insight, that has taught us the value of this power of combination of individuals for the procurement of things indispensable, also instructs us in the usefulness of association for the procurement of things that belong to the luxury of life; and it is accordingly a characteristic of this age, remarkable beyond all former precedent, to build up societies for the encouragement and improvement of the elegant arts. It is a good sign to see a community arrived at that point of moral culture and education at which the people think of establishing these institutions. It speaks of the taste, the refinement, and the virtue of the nation. It tells of the abandonment of the rudeness of unfurnished and unlettered society, and of the substitution of intellectual pleasures for gross and sensual indulgences. It shows us that sober and intelligent industry is attaining its great and glorious aim; that it is arriving at its healthful maturity, and is producing the fruits correspondent to the nature of the seed; that it is making a sound, happy, enlightened nation,—such as all wise founders of states have pictured to themselves when they have laid the foundation of empires. It is good, therefore, to see a people bestow their care upon a liberal support of painting, statuary, architecture, music, and all the other arts which adorn the condition of society.—Amongst these other arts, that of planting seeds and tilling the earth, for the sake of fruit and flowers, holds a place full as high, as worthy, and as excellent as any in the catalogue.

The citizens of Baltimore and its neighborhood have, for many years past, been distinguished for the productions of their gardens;—at least in that most useful department concerned with the cultivation of vegetables and fruits for the table. The climate of this region is eminently favorable to this culture.—Our central position, or middle latitude, enables us, with no great expense or trouble, to rear the plants native to either extremities of this country. We have a soil which, though light, is warm and kindly, and readily submits to the labor of the husbandman. We have sheltered valleys, where the fierce north wind is denied approach; and we have low lands bordering on our river, where the winter is sooner compelled to dissolve his icy fetters, and release the struggling germ from his grasp, than is common to the more elevated table lands westward. Our vegetation, therefore, is earlier, and more easily protected, immediately in this vicinity, than almost on any other spot lying along the same parallel of latitude. These causes have operated to give us good gardens. They have been greatly assisted,—in fact, we may say, these advantages were first shown to us,—by the French emigrants from St. Domingo, who, some thirty years gone by, were exiled by the domestic troubles of that island; and who fortunately selected this city as their asylum. That useful and worthy class of refugees brought with them an invaluable gift to our people—the knowledge of plants and garden stuffs. They were a frugal and industrious race of men, whose

calm and philosophic resignation to misfortune taught us a moral lesson scarcely less valuable than the physical boon with which it was accompanied. Many of them had been affluent, had lived in the abundance of their tropical climate, and, in accordance with the simple and healthful habits of their nation, had accurately studied all the processes of horticulture, and drawn their chief luxuries from that pursuit. They had been despoiled of their wealth; their homes were subverted; and, with the few household relics which haste allowed them to snatch up, they fled before the pursuing war, and reached our shores in safety. On their arrival here, they soon became aware of the value of this position for gardens, and many persons, now within my hearing, will doubtless remember the rapid improvement which took place in the supply of our markets. Almost immediately from the date of this event, Baltimore became distinguished for the profusion and excellence of the fruits and vegetables which supplied her tables. Since that period each coming year has added some new bounty to this valuable resource; our gardens multiply to the full measure of our increasing demand; new plants have been introduced; and an eager emulation has been active to furnish these healthful stores of comfort in the richest variety, and largest abundance.—The poor emigrant has past to the tomb; his generation have become mingled in the mass of our citizens: his humble name may even now be forgotten; but his great and priceless gift survives as a monument of his usefulness, which, although it may not have the glory of the storied urn, nor the splendor of the sculptured column—no, nor the tribute of the deathless page to make it intelligible to posterity, has, nevertheless, an equally honorable claim to the respect of the wise and the good, as a perpetual though silent benefaction to the country.

It is not long since an Agricultural society was established in this state. Its chief object was to promote inquiry and increase of knowledge, in reference to the more extensive concerns of farming. It looked to the production of the crops of grain, the cultivation of grasses, and the improvement of the breed of cattle; in fact, generally to the augmentation of the wealth of the husbandman. I recall this society to mind, that I may appeal to the experience of all who have attended to the impression it has made, for proof of the value of such associations. Our farmers in general, are a highly intelligent race of men, skilled in their particular pursuit, and careful of their own interest, and may be said to have possessed the means of improvement and the disposition to use them, without the aid of societies, as largely as any class of men in any country. Yet it requires no closeness of observation to see how much agriculture has been improved by the labors of this society; what emulation has sprung up to enlighten those who are ignorant, and to extend the field of knowledge for the learned; what valuable additions have been made to the implements of husbandry; what incalculable benefits have been conferred upon the country by the importation of new stocks of cattle; and, above all,—I mention it because the youngest individual in this hall may recognize the fact,—what signal advantages we all have enjoyed in the increased abundance and excellence which has been given to the products of the dairy. It is a pleasant thing to compare the present day with the day that is gone. It is pleasant to live in a country whose condition is ever on the rise; and to see our neighbors, kindred and friends, day by day, growing more comfortable, contented and affluent; to witness the nation growing rich in the substantial blessings of life; the rich man of yesterday made richer to-day, and the poor man of an earlier date brought to the conveniences and comforts of the opulent. It is pleasant to see how marvellously luxuries have grown cheap by the invention and skill of man; and things that were deemed superfluous in one age, converted by the general elevation of society, into the common necessities of the next; to see that which was once the peculium

of the wealthy, by the magic of man's productive skill, brought within the reach of every industrious laborer. These things are pleasant to be thought of; and they make the heart of the patriotic man glad when he reflects that they belong to his country: they make the heart of the religious man thankful, when he remembers them as the blessings of Providence: they spread cheerfulness and content,—the richest of earthly blessings,—over the whole people: they enliven the carol of the ploughman: they brace the sinews of labor, and rob toil of its fatigue: they light up the countenances of the poor; and they make it a happy and enviable thing to the stranger, to have a heritage in this land.

Such may be said to be a picture of our country through the last twenty years. This has resulted, in part, from the natural increase of population and wealth, inevitably incident to a fruitful and peaceful territory, but in great part, also, does it result from the assiduous effort made by individuals and societies to promote the knowledge of the arts necessary to make a nation prosperous, and especially of the arts of husbandry. The press has liberally devoted its influence to the support of this effort. Periodical papers have been ably edited, and munificently encouraged to disseminate science far and wide; the best pens have been employed to make this knowledge common; the air, if I may so speak, has been filled with the philosophy of useful things, and men have absorbed instruction almost unconsciously to themselves. They have caught hints from almanacs, wisdom from the fleeting sheets of a newspaper, precepts from proverbs, and good from all.

In this progress upon the career of improvement our community have arrived at another stage. That stage is indicated by the establishment of the Horticultural Society. The cultivation of fruits, vegetables and flowers no less demands the fostering care of societies, than the larger concerns of husbandry; indeed, from the variety of subjects which this pursuit embraces; from the minute character of its details: from the comprehensive knowledge which it requires; and more especially, from the want of familiarity, in the great mass of our citizens, with the endless processes of this cultivation, it would seem, more than most other pursuits, to demand the aid of intelligent societies, earnestly devoted to publishing the secrets of the knowledge upon which it depends. It invokes the assistance not only of the practical gardener, but of the attentive and astute naturalist; it is concerned not only with the subjects to which our domestic observation has grown habituated, but looks abroad into every quarter of the earth; it explores the treasures of every climate; it studies the properties of every soil; it investigates the peculiarities of every plant; it collects the experience of every people. It is careful to make that vegetation perfect and fruitful which nature has thrown before us in a wild and rugged strength, and to which she has given the promise, that by the nurture of man its fruits should be made abundant; it is skillful, by the arts of grafting and culture, to produce new and endless varieties of species; it is diligent to naturalize and domesticate the rare and valuable productions of distant climes; in short, it brings into the circle of a distinct science the knowledge of interesting facts scattered far and wide over the large surface of nature. The want of a society adapted to this kind of investigation would not begin to be felt until the improving taste of the community, guided by the laudable zeal of public spirited individuals, should take a direction towards the elegant luxuries of the garden. That this taste is growing up amongst us, is abundantly manifested by the zeal with which this first celebration of the Maryland Horticultural Society has been sustained; it is displayed in the rich and rare productions which have been shown for two days past in this hall; it is illustrated by the lively and eager interest of the respectable and intelligent crowds, who, to-day and yesterday, have mingled in this festival of flowers.

There are already several such institutions on this continent, some of which have been in the full career of usefulness for many years past. Their impression upon the people, amongst whom they have been established, has invariably been beneficent; we follow in their steps, imitate their example, and aim at the same good. This society scarcely numbers, as yet, six months since its creation—indeed, the present occasion may be said to be its first announcement to the public—and it is a cheerful and grateful subject of reflection to the patriotic gentlemen who brought it into existence, that their fellow townsmen have so quickly responded to their laudable purpose, and that they have already enlisted the support of upwards of a hundred members. Their little academy promises to spring up to a quick and sturdy maturity, and to win the universal regard of every liberal and enlightened friend of useful knowledge.

The design of every well regulated Horticultural Society, is two fold. It is first, to explore and develop the useful properties of plants; and, secondly, to supply the means of procuring and multiplying the rare and beautiful vegetable productions of nature.

The first department is a large one. It is concerned with the nurture and distribution of that large class of fruits and vegetables, which the provident source of all good has scattered over the face of the earth for the support of his creatures. There is not a climate so fierce, from the inhospitable and howling wilderness of the Arctic—from the far extremities

“— of Norumbega and the Samoed shore,”

down to the

“— utmost Indian isle Taprobane,”

—there is not a barren rock so cheerless, nor a strand so bleak, but that the bounty of heaven has domesticated on it some plant whose substance will furnish subsistence to the living things that there inhabit.—We have brought, from far and near, into our gardens many of the choice dainties which God has bestowed upon the prolific earth: the fruits and vegetables, with which we are conversant, are but few of them native to the soil on which they grow;—the care of man has long ago visited them in their remote homes, and he has preserved the seed, and spread them, in inexhaustible abundance, over all the habitable places of the globe. By an admirable provision of nature they possess the invaluable quality of self-naturalization, and readily adapt themselves to almost every variety of climate where man himself attains his physical perfection. There yet sleep in the solitudes of nature many an unknown weed, whose esculent virtue the prying eye of science has not yet discovered;—they will there sleep in undisturbed obscurity, until the frequent excursions of individuals and societies, impelled by the noble ambition of unfolding these vegetable treasures to the light of day, shall invade their hiding places, and give their humble worth its due share of the esteem of mankind. This enterprise is now busily on foot, and year after year the votaries of knowledge are enlarging their catalogue of the bounties of earth.

Not less important, on the score of usefulness, are these investigations when they are directed to the search after the medicinal virtues of this vegetable creation. The pharmacopœia of medicine is indebted to the labors of the horticulturist for its most valuable ingredients. How many a pain has been assuaged, how many a dreadful hour of suffering averted, how many a life preserved by the simple physic of the garden! Scarcely a plant that puts forth its modest leaves beneath the hedge, nor little root that twists its fibres into the borders of the garden walk, that is not a laboratory of priceless essences, for the relief of some of the countless ills that beset humanity. The power that ordained man to be the victim of feebleness and disease, as if compassionating his inevitable decay, and taking pity on his suffering, has garnered up in these humble cells innumerable speci-

fies, for the possession of which, in his moments of agony, the proudest monarch would barter his crown.

Nor is the excellence of the horticulturist's labor confined to the improvement of vegetation for food and medicine. It has much to do with the subject of affording shade and shelter to our habitations from the intense heat of the summer sky. We may learn by it how to collect and transplant trees; what peculiar attention they require; how their growth may be quickened and their health preserved to make them useful where they are placed. Connected with this subject, too, is a large field of valuable inquiry into the properties and character of our forest trees, with a view to the production of the best and most serviceable kinds of timber—a subject which at no distant day will claim a large share of the attention of our countrymen. The indiscriminate hand of the woodman has long been ruthlessly at work upon our forests, and has already destroyed the resource of great and important wealth to the nation. The diffusion of information on these subjects, may correct the mischievous undervaluing of the glories of our groves, and preserve to future generations a possession which their experience will properly estimate, if ours does not.

Let no one believe that these are frivolous or ignoble pursuits. They are fostered by the care, and upheld by the sillage of the wisest and best men in all ages. The most renowned and illustrious individuals have betaken themselves to the tilling of the earth with a peculiar sense of fresh and lively enjoyment, and in the hours of their brightest triumphs and busiest engrossment have thought of the pleasant earth and its prolific progeny, with a relish rendered keener by contrast with the pursuits of their ambition. It is no mean glory to be the first discoverer of a useful vegetable; nor is his fame to be despised who produces the familiar roots and plants of our gardens in the highest state of perfection. He who succeeds in bringing into existence a turnip or a beet which will weigh ten pounds, when these roots before were not known to exceed two, and who shall teach his countrymen how to repeat the process, confers upon mankind a benefit that should entitle him to a civic crown. He who, by his zeal and research amongst the stores of nature, adds another wholesome and nutritious vegetable to the supplies of the table, as fairly wins a claim to the gratitude of his country as the man who serves her in the senate or the field. The introduction of the potato into Europe, after the discovery of America, may be almost said to have created a distinct political era. It is not long since the tomato and the egg plant,—now classed amongst our most valued and delicious vegetables,—were first given to the people of this land. From whom this boon was derived, is a fact which has shared the obscurity and oblivion common to many of the noblest benefactions to our species. Its value, however, is attested by the universal favor with which it has been received. It has been said, by some impassioned epicure, that that man is entitled to the thanks of his country who invents a new dish. It such should be his glory, how much more signal should be the fame of the man who, by discovering a new and savory material, should lay the foundation of twenty dishes—who, instead of spending his genius upon another mode of combining and concocting the already known elements of good living, carries his research into the field of unexplored aliment, and brings into the kitchen some before unheard of, rich, flavorful and healthful nutriment.—What renown would await the gardener or the herbalist, who should succeed in transplanting to our soil, or who should discover in the mold of our forests that most boasted of all European condiments—that matchless and priceless flavorer of soups, pasties and ragouts—that most catchrestical dainty, of which it glorifies a man to be able even to speak in our country,—since it shows that he has had the benefit of the Trans-Atlantic tour—I mean the far-famed

truffle! Truly, that man's name should be well remembered! I can imagine with what sincere affection it would be lauded by the hungry man who sat himself down, for the first time, to a repast where this rare seasoner lent its flavor to the viands; how acute and pleasant would be the recognition of the man of nicely adjusted palate at the same banquet; how thankfully the invalid, with sickly and sated taste, would express his sense of the benediction when he found it reviving, stimulating and charming his jaded and capricious appetite. These, I repeat, although they concern our sensual enjoyments and furnish appliances to our baser desires, are nevertheless no mean glories. They contribute innocent allurements to beguile man from the knowledge of the weariness of his earthly pilgrimage; and they corroborate and fortify his body by giving him health and strength, and cheerfulness and content—the better to enable him to discharge these higher and more noble offices which belong to his condition as a thinking, aspiring, and accountable being.

To all such purposes the Horticultural Society is eminently subservient. It not only invites and persuades men to give their attention to the introduction of new vegetables; but it also teaches how those in use, native or naturalized, may be produced in the greatest abundance, with the least labor, and at the earliest periods of the year. It studies the nature of plants, their characters, their habits, the things and conditions congenial to them, and the obstacles that embarrass their increase. It teaches what distemperatures are incident to their growth; what signs attend their career, whether for good or ill; and with what profit these may be observed. In fact it builds up a beautiful system of georgics, which the philosopher may study with delight, and the practical gardener may pursue with advantage. It furnishes a fruitful source of emolument to the poor, and opens new fields for the employment of wealth, and a thousand new channels for the distribution of it amongst the laboring classes. Its purposes are good, and its means of reaching them wholesome. Such are its more immediate useful aims.

Its second design is to cultivate a taste for ornamental vegetation, and to contribute to the pleasures of the eye. I should be wanting in my duty on the present occasion, if I did not descant upon this branch of the labors of the society.

A garden is a theme of pleasant recollections to us in every stage of life. We remember, with a peculiar fondness, those days of infancy which were spent in playing through the labyrinths of the trimmed hedges of box, and where the althea, the lilac and the hawthorn, bounded the parterre, over which we struggled with heedless step and with hearts as gay as spring itself, amongst tulips, hyacinths and marigolds, as they clustered about our knees. The odor of the new blossom is still fresh and unforgotten in the recollection of our childish sports, when we mischievously shook the blooming fruit tree, and stood beneath the shower of its dazzling petals, in whose fall we had thoughtlessly robbed the year of its promise. In manhood the same images visit the senses with undiminished delight. In old age they come again with their usual freshness; as if that love of nature, that rapturous enjoyment of her beauties, were the only sense that time could not blunt, nor use destroy.

I do not envy that man who, at this season, can go forth from the city to the woods, and as he threads some winding rivulet, with its little cascades and rocky currents, can set his foot upon the modest violet, without feeling an interest in its simple history, or a pleasure at finding himself in the secret home of the wild flower. I do not think well of him who does not count himself a better man for being where nature has spread her untrimm'd beauties before his eye, and poured upon his ear the gush of her fountains. He is not to my liking who cannot acknowledge to himself a new transport, when, at this fragrant and blooming time, he finds himself surround-

ed by the profusion of flowers which, unplanted, shoot up in every glen and on every hillside, over every field and through every grove—the gay tribes of the azalea, the rich kalmias, and the perfumed sweet-briar.

"Flowers worthy of Paradise, which not nice art,
In beds and curious knots, but Nature boon,
Poured forth profuse, on hill and dale and plain,
Both where the morning sun first warmly smote
The open field, and where the unpierced shade
Imbrown'd the noontide bowers."

To me it seems that we are affined to our mother earth by an instinct, which civilization and artificial life cannot subdue, that makes us love the green leaf and the "crisp'd brook." That this instinct, after years of absence and disuse, still conjures up and renews without abatement its appropriate emotions of delight; when the objects to which it is allied recur to view; like that mysterious sense of recognition which is said to exist in the bosom of the child who, long separated from his parent, meets her, when no knowledge of her voice and features might recall her to his memory, and who is nevertheless conscious of her presence by the inward moving of a principle within him, that speaks to his heart with an almost supernatural inspiration. I have read of the young savage taken early from his native woods and indoctrinated in all the lore of the schools, trained to the usages of civilized life, secluded from all knowledge of his native haunts; yet when, at manhood, he has been left to pursue the bent of his free will—the first fanning of the mountain breeze—the first rustling of the forest leaf—the first gush of the clear river has awakened his dormant but indomitable instincts; and, breaking through the sophistications of his guarded life, he has rushed wildly and in the ecstasy of his long-repressed but now regenerated impulses, to the kindred wilderness of his fathers. Such seems to me to be the nature of that quick recognition of rural beauty, which affords so much satisfaction to the heart of every well constructed man, when he finds himself remote from the populous city, and embosomed amidst the verdure of hill and valley, and shaded with the fresh leaves of spring.

It is to minister to these pleasures, to enlarge their field, and to prolong their duration, that the Horticultural Society, amongst other things, directs its aim.—The cultivation of flowers admits of almost endless research. It is wonderful to observe how much the hand of man has done to produce variety and luxuriance in every species of this vegetable creation; and how his skill has mastered the secrets of their organic laws, and enabled him to give them new hues and shapes. Who has not seen the color imparted to the hydrangea by the change of the mold around its root? Who has not admired the infinite varieties of the tulip, the rose, and the carnation? Who has not contemplated with pleasant surprise the effect of cultivation in enlarging, redoubling, and expanding the structure of some of the most beautiful flowers of the garden? The knowledge which achieves these marvels deserves regard, not only as it furnishes us a philosophical amusement, but from the higher consideration, that it illustrates the labors of the naturalist, and unfolds the mysteries of the operations of that universal providence which fills this world with good and beauty.

There are many attributes of a moral cast belonging to the rearing of plants. These little earth-born toys, speak to us a volume of pretty histories; they are domesticated with us, and partake of our household affections; they are symbols of the most agreeable thoughts and sentiments; they are consecrated by ancient custom to our amusements, our business, our fancies, our superstitions, and to our religion. He who will read the history of our race, will find that in all ages they have had curious mystical associations with our being; they have been our oracles, our monitors, our talismans. The credulity of our ancestors has invested them with virtues, that supposo

them to be the peculiar favorites of the invisible agents which were believed to sway the destiny of mortals; and prescription, as hoary as our earliest tradition, has assigned to them a special function in the business of life: the laurel and the bay were supposed to be girted with the power of parrying the thunder-bolt; and they have formed the appropriate wreath of the hero and the poet: the ivy and the holly, the palm and the cedar, have for centuries typified to the pious and reverent mind, the mild and unfading lustre of christianity; and, even at this day, furnish evergreen garlands to decorate the festivals of the church. What countless recollections, mellowed by the bland and rich light of poetry, are clustered around the little sprig of rosemary! How does its very name conjure up the image of the wedding and its gay train, the wassail bowl, the joyous dance, and all the pomp of the festive hall! How does it recall the Christmas carol, and the old ballad, which rehearses in simple, uncouth verse, the merry-makings of that laughing race, who, many generations back, were as intent as we are now, to cheat life of its pain, and dall the edge of the scythe of time! The misletoe is scarcely less venerable in the Druid's faith, than in the respect of our immediate progenitors, who held it sacred to the service of the funeral. A mournful, yet not unpleasing sadness hangs around the melancholy yew and cypress dedicated to the silent solitude of the tombs. In the Romish calendar, there is not a day in the year without its saint, nor a saint without a consecrated plant: even the passion of the Saviour, by a beautiful conceit, is supposed to be recorded on the disk of a familiar garden flower, and to the religious mind serves as a memorial of the most sublime event in the annals of the human family.

Then, too, this world of flowers, how does it speak to us of the fairy enchantments, and wonder-working spells of that superstition, which built up the rich and homely mythology of the gone-by time!—of the slip of rue, which could set at naught and defy the malice of the meagre hag!—of the "vervain and the dill," that, according to the ancient couplet, had virtue to "hinder witches of their will!"—of the moonwort, which, if the legends say true, could unbind that which was fast, open double-bolted locks, and even snatch the shoe from the horse that set his foot upon it! How does it summon up to the imagination, the gorgeous and gaudy realms of Oberon and Titania, with their tiny mignons peopling the labyrinths of the rose, diving into the well of the honey-suckle, or sporting beneath the tent-like canopy of the inverted lily! and how remind us of that prankish sprite, who was wont to vex the household of our "idle headed eld,"—Robin Goodfellow,—lurking, as Shakspeare has pictured him, in the cowslip's bell, and sharing in the plunder of the bee, or sleeping amidst the odorous tapestry of the jasmine and the woodbine! The whole theme is redolent with the richest essence of poesy, and delights the mind as much by its association with the racy tales of genius, as the flowers themselves regale the senses by their forms of unmatched grace, their delicate hues or exquisite perfumes.

This floral department cannot but find favor with the ladies of Baltimore: its care is peculiarly within the province of their sex, and it therefore, constitutes an essential and valuable feature in the organization of the Horticultural Society, to enlist the zeal, and insure the co-operation of our townswomen, by soliciting them to become members of the society, and to assume an active participation in its duties. Under their control, and with the aid of their spirited devotion to our purpose, we hope to communicate an impulse to the public, which must speedily make this institution popular and productive of the greatest good. We have already, so far found grace in their eyes, as to attract the regard of several of the most intelligent and praiseworthy individuals of the sex in our city, whose names are now enrolled upon our records, and we do not doubt that their excellent example will be promptly followed by their companions and friends.

It is in the power of our fair compatriots, not only to enliven and refine the taste of this community, but to bestow a grace and a vigor upon the endeavors of this society, which, without them, it might in vain struggle to acquire. To them, therefore, we strenuously appeal for support, and trust that they will attach themselves to this institution with that ardor which forms a part of their character. Then may we expect that our festival of flowers, in each succeeding year, will be truly a banquet of delights; where beauty shall rule the hour, and joy walk in the footsteps of usefulness; where good and pleasure shall go hand in hand, to exalt, adorn and dignify the aims of the society, and our city win a fresh chaplet of fame for its virtuous devotion to these refined and bountiful pursuits.

From the sketch which I have imperfectly given of the nature and aims of this society, it will be seen that we stand in need of the commendation and support of our fellow citizens at large, and that our organization is one which may furnish the opportunity to do much good under the most agreeable and alluring forms. We ask no personal sacrifice from any one, of time or money, which might be employed with more profit in gratifying the demands of the other relations of life. We wish to give a direction to the tastes of our people, and rather train their recreations and their pastimes to pursue a channel which shall be no less fruitful in enjoyment, than their more customary pleasures, yet, which shall, at the same time, increase the store of comfort to all. We offer to the votary of our cause an occupation that engrosses the mind with innocent and peaceful duties; that inspires pure thoughts, elevates and refines the heart, and raises man to a love for simple and virtuous amusements; that infuses health and vigor into his veins; that fills his thoughts with subjects calculated to allay the irritations of life, and that exalt him to the worship and imitation of his God. We offer him an employment that shall make him conversant with green fields, and running brooks, and balmy skies;—a pursuit that shall warm his fancy to the relish of the beauties of nature, and that shall teach him to despise the tinsel and trickery of artificial life, by the fresh perception it will give him of the luxury of the "unceased air," and of the never-sating joys of the forest and field, of the woodland slope and flowery mead;—a pursuit, of which it is its chief glory and highest praise, that "all its ways are ways of pleasantness, and all its paths are peace!"

(From the Atlantic Journal.)

SULPHUR IN TREES. TO DESTROY ALL INSECTS PREYING ON THEM.

Farmers and gardeners ought to hail with rapture a safe, certain, easy and unfailing mode of driving away or destroying all the insects, bugs, caterpillars, lice, ants, which prey upon trees and often kill them.

Numberless have been the means proposed or devised to get rid of these troublesome guests, most of which are dirty, costly, or unavailing. Our farmers appear to have given up in despair the hope of preventing the deadly attacks of *curculios* on the roots of peach trees, and the fruits of the plum tree. Yet an efficacious mode is said to have been found several years ago in France, perfectly efficacious and applicable to all cases and all trees. The man who discovered it, deserved a splendid reward, yet his name has not even reached us. But we claim the honor to have been the first to make known the process in America, in 1823 in Kentucky, and in 1827 in Philadelphia. Yet the most useful knowledge is so slow to spread, that the fact is hardly known yet, or doubted by those who know of it.

We are happy to be able to publish two direct experiments in support of the fact and discovery.

1st. We bored and plugged with sulphur in the usual way, a plum tree which commonly dropped every year all the plumbs before becoming ripe, the

curculios lodging eggs in their germs. This was done when the tree was in blossom. On that year hardly any fruit fell, and the tree produced quite well.

2d. We find in the Genesee Farmer, of January 28, 1832, that a young willow nearly killed by aphids or lice, and pissuities feeding on their honey, was quite revived in three days, and all the lice and ants driven off, by boring the tree with an auger five feet from the ground and three-fourths through the diameter, filling with brimstone and plugging tight. The tree has thrived ever since.

The modus operandi of this singular process is very easy to explain. The vital energy of the tree and sap, dissolves the sulphur, carries it into circulation, and involves it in sulphuric gas evaporating through all the pores of branches, leaves and fruits. This gas is a deadly poison to insects and all animals, it suffocates them or drives them away as soon as they begin to smell it; but no injury whatever results to the tree.

We have never heard yet of any direct experiment on peach trees; but we are sure it will answer quite as well. If the sulphuric emanation could not reach quick enough the roots of the trees which are commonly attacked, the plugging must be done near the root or at the time of the descending sap, when it will sooner reach the roots. Let it be tried and the results made known. C. S. R.

(From the Abbeville Whig.)

DOMESTIC SILK IN SOUTH CAROLINA.

When on an excursion to the country a few days since, we found, much to our surprise and gratification, that some of our female friends had turned their attention to the culture of silk; and that many of them had made such progress in this laudable experiment, as already to have realized considerable profit from the production of the raw material, and manufacturing it into cloth. Mrs. Patrick Calhoun, of this District, who, among her other many excellent virtues, is remarkable for her industry and attention to her matters of domestic concernment, showed us in a house which she had fitted up for the purpose, at least, we would say, one hundred thousand silk worms, all healthy and busily engaged, some of them in forming the cocoon and others fitting themselves for the production of that valuable material. Mrs. Calhoun, who had tried the experiment last year on a smaller scale than she is doing the present, assured us that she had no doubt should no unforeseen accident occur, she would be able to raise silk enough by the latter part of August, to manufacture more than a hundred yards of cloth.

We know of two other ladies in this District, Mrs. Covington and Mrs. Baskin, who have been similarly engaged for several years, and we have seen some pieces of silk cloth manufactured by them, which, when worked up into clothes makes a beautiful and lasting dress. The cloth manufactured by them has sold at this place for \$3 per yard, and it is sought for with avidity, not only on account of its rarity, but also for its beauty, durability and cheapness. We hope that our ladies will turn their attention to this interesting, profitable, and laudable employment, and that we will be pardoned by those whose names we have given to the public, for having done so without their permission.

FINE PRICES FOR TOBACCO.—The following fine prices were obtained for tobacco, at Lynch's warehouse, during the last week, viz:—A crop of 4 hds. made by Mr. Benjamin Halliborton, of Person county (N. C.) was sold on Tuesday last, one for \$12 50, one for \$12 25, one for \$10, and one for \$6, averaging \$10.184. Two hds. made by Mr. Byrd L. Ferrel, of Halifax, were sold on Wednesday, at an average of \$11.—Three hds. of the crop of Mr. John Owens, of Pittsylvania, were sold, one for \$12 and two for \$10 each. And on Thursday, a hhd. made by Mr.

William P. Thomas, of Pittsylvania, was sold for \$16. The last named hoghead was very much damaged, by an accidental exposure to rain, but for which circumstances, it is thought, it would have brought from eighteen to twenty dollars.

(Lynchburg Virginia.)

TURNIP SEED.

For sale the following kinds of Turnip Seed, of the very first quality, at \$1 per pound.

EARLY WHITE DUTCH.

GARDEN STONE.

WHITE FLAT. GREEN ROUND.

RED ROUND OR RED TOP.

WHITE NORFOLK. WHITE TANKARD.

YELLOW ABERDEEN. RUTA BAGA.

And, as usual, a complete assortment of GARDEN SEEDS generally.

I. I. HITCHCOCK,

American Farmer Establishment.

BUCK WHEAT.

A few bushels of very superior quality for seed, for sale at the American Farmer Establishment, at \$1.25 per bushel.

I. I. HITCHCOCK.

N. B. Half a bushel is required to seed an acre.

IMPROVED DURHAM SHORTHORN CATTLE.

I have the selling (on commission) of the following fine animals,—viz:

A Bull 5 years old, full blood, for	\$200
Do 3 " " Do "	300
Do 2 " " Do "	250
Do 1 1/2 " " Do "	250
Do 1 " " (small) Do "	150

Several Cows and Heifers from \$200 to \$300 each.

Half Blood and upwards.—A Bull Calf, by Bolivar, 6 months old, fifteenth-sixteenths Durham Shorthorn, very promising, \$75.

A Cow 8 or 9 years old, seven-eighths Durham Shorthorn a very fine breeder, \$100.

Several Heifers 2 years old, half blood and upwards, prices from \$75 to \$100 each.

Several similar Heifers 1 year old, \$50 to 75.

Several half blood Bulls, 1 year old, \$30 to \$50 each.

Address I. I. HITCHCOCK.

Amer. Far. Office.

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale.

Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life,) is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also,—A young JACK, a son of Don Carlos, 4 years old, 43 inches high, well made, stout and promising, of same color as his sire—price \$200.

Also,—A full sister of the last, 3 years old, 44 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

I. I. HITCHCOCK,

Ap. 26—tf. Amer. Farmer Establishment.

HERBEMONT ON THE VINE AND WINE MAKING

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States. By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents

WANTED,

At the American Farmer Office and Seed Store, all kinds of GRASS SEED, CLOVER SEED, and choice Domestic Animals. Apply to

I. I. HITCHCOCK.

TWO IMPORTED MALTESE JACKS FOR SALE.

These animals were purchased in Malta in June, 1832, for two officers of the U. S. ship Concord, in which they were imported. The selection was left to one of the best judges in the island, who advertised three months previous to purchasing, for the largest and best bred Jacks, without regard to cost—more than one hundred were offered before a choice was made. They are now about three years old, and stand, one 13 1/2 and the other 13 1/4 hands high, and will yet grow three or four inches: their color is black with fawn nose, eyes and belly. In size, action and vigor, they were believed to be unsurpassed by any Jacks in Malta, and they have been pronounced by good judges, the finest ever brought into the United States. It is deemed unnecessary to say any thing about the superiority of the Malta Jacks; it being well known that they are of the high bred stock of Persia and Arabia.

These animals may be viewed and every information respecting them, may be obtained, by applying to I. I. Hitchcock, American Farmer establishment, Baltimore. The price is \$600 each.

HARVEST TOOLS, WHEAT FANS, &c.

SINCLAIR & MOORE, have in store, and are manufacturing a general assortment of HARVEST TOOLS, among which are

100 WHEAT FANS, double and single geared.

300 Grain CRADLES, with Seythes complete. This article is made of the best and most durable materials, and will be warranted as such.

50 doz. Grass and Grain SNEATHS.

30 doz. Hay and Manure FORKS.

30 doz. RAKES and Wooden tined FORKS.

SCYTHES and Sneaths, hung ready for use.

SICKLES, English and American Seythe Stones, Strickles, &c. &c.

Their Stock of CASTINGS, Agricultural Implements, Garden Tools and SEEDS, is as usual full and complete.

Also, just received from Europe, two bales, containing Lucerne and Ray Grass, Cabbage, Radish, Lettuce, and many other valuable SEEDS of last year's growth. From the appearance of this lot of Seed; and the respectability of the establishment from which they were imported, they can with the greatest confidence recommend them.

May 24.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Conave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street.

Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—Some slight variations will be noticed in our quotations of flour. The wagon price of Howard street flour fluctuates between \$3.37 1/2 and \$5.50, according to freshness and brand—fresh ground of good brands commanding the maximum. The store price of this article also varies according to the same circumstances. There is also a slight variation in the prices of grain, and for prime lots our highest rates are readily obtained, while ordinary and inferior are dull.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 432 hhds. Md.; 220 hhds. Ohio; 2 hhds. Ken. and 1 hhd. Penn.—total 654 hhds.

FLOUR—best white wheat family \$6.75 a 7.25; super Howard-street, 5.62 1/2 a 5.75; city mills, 5.62 1/2 a —; city mills extra 5.57 1/2 a —;—CORN MEAL bbl 3 62 1/2;—GRAIN, best wheat 1.12 a 1.18; white do 1.25 a 1.31;—CORN, white 60 a 61, yellow, 62 a 63;—RYE, 65 a 67;—OATS, 36 a 38.—BEANS, 75 a 80.—PEAS, 65 a 70.—CLOVER-SEED 5.00 a —.—TIMOTHY, — a —.—ORCHARD GRASS 3.00 a —.—Tall Meadow Oat Grass 2.00 a 2.50.—Herd's. — a —.—Lucerne — a 3 1/2 lb.—BARLEY—FLAKE 1.37 a 1.50.—COTTON Yd. 11 1/2 a 13.—Lou. 12 1/2 a 14.—Alab. 11 1/2 a 13.—Tenn. 11 a 12 1/2; N. Car. 12 a 13; Upland 12 1/2 a 13 1/2.—WHISKY, hhds. 1st p. 28 a; —in bbls. 31 a 32.—Wool, Washed, Prime or Saxony Fleece 45 a 50; American Full Blood, 38 a 42; three quarters do. 33 a 38; half do. 30 a 33; quarter do. 28 a 30; common 25 a 28. Unwashed, Prime or Saxony Fleece, 25 a 30; American Full Blood, 22 a 25; three quarters do. 20 a 22; half do. 18 a 20; quarter do. 16 a 18; common, 16 a 18. HEMP, Russia, ton, \$195 a 205. Country, dew-rotted, 6 a 7 c lb. water-rotted, 7 a 8 c.—Feathers, 37 a 37 1/2.—Plaster Paris, per ton. — a 4.25; ground, 1.50 a — bbl. Iron, gray pig for foundries per ton 33.00 a —; high pig for forges, per ton. 28.00 a 30.00; bar Sns. per ton, 75.00 a \$5.00.—Prime Beef on the hoof, 5.75 a 6.50.—Oak wood, 3.00 a 3.25; Hickory, 4.00 a 4.50; Pine, 2.00.

CONTENTS OF THIS NUMBER.

Editorial: Horticultural Address; American Nankeen; Sunflower Oil; Great Grapevine—Report of the Committee appointed by the Horticultural Society of Maryland to award the Premiums at their First Annual Exhibition—Preserving Bees—Account of an Agricultural Excursion, made into the South of Georgia, in the Winter of 1852, by John D. Legare, Editor of the Southern Agriculturist; continued—On the Improvement of Agriculture in Virginia—Address delivered before the Horticultural Society of Maryland, at its First Annual Exhibition, June 12, 1853, by John P. Kennedy—Sulphur in Trees to destroy all insects preying upon them—Domestic Silk in South Carolina—Fine Prices for Tobacco—Prices Current of Country Produce in the Baltimore Markets—Advertisements.

The American Farmer,

Edited by GIDEON B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum; due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect AT THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

5. DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "J. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, JUNE 28, 1833.

THE FARMERS' REGISTER.—We have received the first number of a new and valuable agricultural journal, with the above title, published in Richmond, by Edmund Ruffin, Esq. of Garysville, Va. The qualifications of Mr. Ruffin for conducting such a work, are unquestionably very high. He comes before the public with a mind well stored, and a pen thoroughly practised in the field of experience; and when we add, that these are accompanied by a spirit entirely devoted to the important interests he has undertaken to advance, we think it but the simplest effort of human reasoning to conclude, that complete success must attend his efforts. Mr. Ruffin has been an agricultural writer for many years, and the pages of the American Farmer bear ample testimony to his merits as such. His Treatise on Calcareous Manures, lately published, would be sufficient of itself to establish his high claims to public confidence. But the number of the "Farmers' Register," now before us, furnishes further evidence of his qualifications for the duties he has assumed; and, as it will be upon its own merits, at last, that the work must depend for success, this number offers high encouragement to both patron and Editor.

We shall copy into the American Farmer, whatever we find in the Register of sufficient interest;—it will of course be inferred, from what has been said above, that our extracts will be very copious. In wishing the most complete success to the Farmers' Register, we may be allowed to say, that we do so with the sincerity and earnestness of the patriot, rather than from the dictates of affected courtesy. That our immediate interest will be injuriously affected by the publication of Mr. Ruffin, there is no room for question; but that the American Farmer will ultimately be benefited by it, and our interest thereby enhanced, there can be as little doubt. We have lost some subscribers, who have exchanged ours for Mr. Ruffin's journal; but we shall more than replace them with others, who shall be awakened from the apathy of thoughtless indifference by the spirit excited by an increased circulation of agricultural writings. We flatter ourselves also, that we shall be able to render our own work more valuable by the selections we shall make from the Register; and that this new publication will be a spur to excite us to more exertion, so that the readers of the Farmer cannot fail to be greatly benefited by the commencement of this valuable cotemporary.

DIONEA MUSCIPULA.—Fenn's Fly Trap.—We are indebted to a much respected friend for a few of these very curious plants, which he found growing in the neighborhood of Newbern, North Carolina. He will please except our thanks for them. In his letter accompanying them, he remarks, that the best account of this singular plant that he has met with, is in Mr. Nuttall's Genera of North American plants, a work of great accuracy, and invaluable to the student of North American Botany, although it gives only a catalogue of the species with occasional specific descriptions. When this work was published, (1818,) the Dionea was only known to botanists as existing in the neighborhood of Wilmington, in North Carolina, on the north side of Cape Fear river, where Mr. Nuttall saw it, and traced it fifty miles up that river.—Our correspondent first saw it in Bladen county on Black river, a tributary of the Cape Fear. Two years ago, Dr. Loomis, of Newbern, and our correspondent, found it in the neighborhood of Newbern, where it had been previously known to some persons ignorant of botany, but who regarded it, nevertheless, as a curiosity. Recently, in passing through the county of Duplin, N. C. the latter gentleman found it very abundant in the wet pine barrens of that

county, associated with *Sarracenia flava*, and the *Liatris ordostratissima*. It was in flower in the first week of June.

Our correspondent, states also, that he saw in Florida, the *Magnolia macrophylla* (large leaf magnolia) in full flower about the middle of last April. This, he observes, is a new locality of this splendid tree, hitherto one of the peculiar boasts of the rich Botany of North Carolina. The editor of the American Farmer, paid a visit to the spot in Lincoln county, N. C. where this tree was supposed to be alone found, in 1820, and will never forget the splendid bloom he there saw. It was eight or nine miles south of the court-house, in a wild and dark forest.—The *Magnolia macrophylla*, grew in a grove of a few acres, and appeared to be confined to that locality exclusively, as, though he travelled through a great part of western Carolina, he found no specimen of it any where else. Our correspondent also remarks that the *Magnolia aculeolata* begins to bloom in Florida about the 25th of March, the stately *M. grandiflora* about the 25th of April, and *M. glauca* on the 12th of May.

Let us beg of our friends, *every where*, to enable us to disseminate such information as the above, by furnishing us with the materials. However trifling many of them may consider such information, we can assure them that it is very interesting to many of our readers. Our correspondent, from whose letter we have extracted the above facts, will please accept our thanks for them, and we beg of him further favors of the kind. In these days, when the march of mind is at quick step, pens like his should not remain idle.

We shall immediately act upon his suggestion relative to a "complete Flora of North America," but think it best to consult the gentleman he refers to, privately, before we take up the subject publicly.

VALUABLE MEMORANDA.—A friend in North Carolina has sent us the following brief extract from his memoranda. If all our subscribers in the United States, would send us the date of blooming of these trees, at their respective places, we could construct a table of great importance, from which the exact difference of the seasons between any two sections of the union, and between any two counties, could be seen at a glance.

Extract—June 1st, 1832. *Chionanthus virginicus*, (Fringe tree,) and *Kalmia latifolia*, (mountain laurel,) in bloom in the valley of the Patuxent, near Baltimore.

April 1, 1833. *Chionanthus virginicus* in bloom, and *Kalmia latifolia* beginning to bloom in middle Florida.

EARLY TOMATOES.—Ripe tomatoes were sold in market on Wednesday, 19th inst. by Mr. Freize's gardener. These we believe were the first this season, and we notice the fact that they sold readily at 50 cents a dozen, for the encouragement of other gardeners.

VEGETABLES FOR PREMIUM.—Gardeners will do well to remember that any vegetables that they consider very early or remarkable in quality or kind, may be left at the Office of the American Farmer, where they will be examined by a committee of the Horticultural Society, every Saturday morning between 8 and 9 o'clock, and receive such premium as they may be entitled to.

✂ We have received an excellent article from J. H. Craven, Esq. giving an account of his system of farming, which we shall publish next week. We regret that it did not reach us in time for the present number. Our agricultural friends in Virginia, may expect something valuable in this article. We take this occasion to request Mr. Craven, to continue the use of his pen in this way. The subject of deep and horizontal ploughing, &c. is worthy of his attention;

and, as he has had forty years' experience in agriculture, and been an observer as well as practitioner of horizontal ploughing, our readers cannot fail of being benefited by his writings.

TURNIPS.

Extract of a letter from a correspondent in England, to Wm. Prince & Sons, of the Lin. Bot. Garden, respecting the Turnip culture in that country.

The different sorts of turnips are sown thus, the Swedish at the end of May, or first of June, a few of the Tankard are sown about the same time, and about the middle of June to the end of that month the Globe is sown, and after these the yellow sorts. Some farmers sow the yellow varieties before the Globe, but as they are very early turnips, and apt to mildew when a drought sets in; we recommend them always to be sown last. The Tankard is not generally sown, except for very early eating by cattle, in the month of September, and in most cases the white Globe is preferred, it being a much more solid root, and if sown equally early superior to the Tankard. The later sown Globe follows in succession—about the month of January the yellows come in, and after them for spring feeding the Swedish; which, when pitted before the frost sets in and kept dry, will remain perfectly fresh and good till the month of June, if that is desired, but here our cattle are, before that period, either sold fat, or put out to grass. The Swedish turnip stands a great deal of frost, indeed there are few winters in which they are injured by it—but there ought always to be a quantity stored, to be used for food during snow storms. Horses are here fed during the winter with a few of them daily, along with their other food.

N. B. Wm Prince & Sons have imported above a thousand pounds of the above turnip seeds. They may also be obtained at the American Farmer Establishment.

(From the Vermont Chronicle.)

BEES.

MESSRS. EDITORS.

May 20, 1833.

A variety of expedients have been devised to prevent the entrance of the bee moth into bee hives. I am not well satisfied with any I have seen, though they may be of some use. I beg to propose a new one; and that is, a rope of cotton wool, extending from the entrance of the hive round to the entrance again; and if thought necessary, another around the top of the hive. Indeed, put cotton wool somewhat loose, in or on all places where the moth will incline to lay its eggs. It may be well to sprinkle the cotton with fine salt. If the rope becomes wet and adheres to the hive or bottom board, a new rope may be substituted. *The reason of the thing:* Insects in general, and moths in particular, avoid cotton wool, as a *nidus* for their eggs, probably because they are so easily caught by its threads, and because there is no oil in it as in wool. Bees themselves will not walk upon it. Salt too is avoided by insects as a *nidus*, and by sprinkling the cotton with that, it may be still more uncomfortable to the miller.

The experiment is so simple, I hope it will be tried. In general, if a hive is well stocked with bees there is not much fear but they will manage to guard the entrance, if the apertures are not too large.

J. W.

EXTRAORDINARY OX.—A remarkably fine six year old Durham ox, bred and fed by E. B. Vaughn, Esq. of Burway, near Ludlow, was slaughtered by Mr. Lea, jun. of this city. The carcase weighed 98 score 5lbs. (or 1,665lbs.) rough fat 200lbs.; rump 132lbs.; sirloin 154lbs.; hide 147lbs. Over the first rib the depth of fat was 9 inches, and from 4 to 5 inches on the sides. The individual who bought the rump cut off a steak which weighed 11lbs. When alive the ox stood 17½ hands high.—*Worcester (Eng.) Journal.*

AGRICULTURE.

(From the Farmers' Register.)

SPECIFIC MANURES—CLOVER—FIELD PEAS.
MR. EDITOR: May 18, 1853.

Sir,—I have long wished the publication in eastern Virginia of a paper similar in character with that which the prospectus of the Farmers' Register indicates. From it, I confidently anticipate important improvements in our agricultural operations, as well as an increase in the fertility of our farms, surpassing what had (until within a few years,) been hoped by the most sanguine proprietor. Under that excitement, and perceiving that you invite the transmission of agricultural notices of even minor importance, I have determined to send this paper, in aid of what I deem a laudable adventure on your part—leaving it entirely in your discretion to publish or suppress it.

No intelligent agriculturist hesitates to admit that the deterioration or increased fertility of our farms depends essentially on the greater or less quantity of animal and vegetable manures spread on them, and that to increase the amount, ought to form a primary object in the operations of every intelligent proprietor—still, as valuable auxiliaries are doubtless attainable, it becomes our duty to seek after them with greater assiduity than has as yet been manifested. The resemblances in the animal and vegetable kingdoms (so numerous and so obvious as to induce the most intelligent writers on natural history to class them as beings of the same order, and that nature passes from the one to the other by imperceptible degrees) afford an unbounded field for investigation, and when explored, will, I am persuaded, furnish invaluable instruction.

It is highly presumable when man first subjected the horse, ox, &c. to his control, as nature apparently had provided only green vegetables for their subsistence, that he, confiding in her unerring wisdom, also deemed other food superfluous; but the earliest records of history present those animals participating with their masters in the use of corn, and experience evinces that in their increased bulk and muscular strength we are amply remunerated. The dog rejects vegetables; and although he can subsist on bread, yet if entirely deprived of flesh, (the food most congenial to his nature,) it will be attended with a proportionate decrease of strength and courage. Birds and fish in like manner require for their maturity that aliment which is adapted to their different constitutions. The vegetable kingdom sustains the analogy. Animal and vegetable manures are congenial to the growth of every species of vegetables; and yet the locust if planted in a soil the most fertile, but defective in lime, like the dog feeding on bread, although sustaining still its growth, bears no proportion to trees of like kind on utterly exhausted hillsides abounding with marl. The pine on the contrary, luxuriates on soils worthless for the production of food for man or beast beyond any tree of the forest; but if transplanted into a highly calcareous soil, however abounding with putrescent vegetables, its growth announces uncongenial food, and like the sheep sorrel, it seems (from the presence of lime) divested of the power of feeding on the abundance of manure by which it is surrounded. This discrepancy, common to animals and vegetables, serves more obviously to illustrate the similitude in nature's works, and should teach us that discrimination in food which experience has ascertained to be indispensable to the improvement of the animals under our immediate care and observation, is equally expedient in our agricultural operations; and as that unerring instructor has shown that vegetables, spontaneous in growth, are inadequate to the perfection of animals, we should infer their incompetence, when rotted, to perfect the variety of the species of plants which we cultivate: and this suggests the expediency of our exploring that portion of the earth itself accessible to us, to discover, if possible, any combinations within, congenial to the growth of vegetables,

which, from their position, are inaccessible to the roots of growing plants.

I am the more confident in advising other agriculturists to institute similar investigations, from an experiment with *gypseous earth*, made under anticipations of success so feeble, as barely to buoy me under the operation, on one acre of land—because I then was, as I now am, uninformed of the quantity of the sulphate of lime per bushel, and knew not the duration, if any, of its nutritious effects on the growth of clover or other grasses; but at this time, I appreciate the consequences of my trial as far more important than any other (the use of marl always excepted) which has ever come under my observation.

Corn was cultivated in 1831, on a sandy ridge in my field, marled in 1826, and yielded from eight to ten bushels; it was seeded with wheat in October, and clover seed (in the chaff) sowed in December following, and soon after from forty to fifty bushels of gypseous earth carelessly spread on an acre. In June, the number of plants, and the growth of the clover, palpably marked that portion on which the gypseous earth had been thrown, and was to me exhilarating indeed—while the yellow and feeble aspect of the pretermitted spaces, under any other circumstances, could not fail to deter every prudent farmer from adventuring a second crop of clover on a similar soil. The wheat languished, and appeared neither cherished or damaged by aliment the most nutritious to clover, by which it was surrounded, and scarcely yielded a recompense for its cultivation. This spring, appearances are equally flattering, the clover being about two feet high, and a space of thirty or forty acres, which was spread last fall with the same earth, fully sustains the character of this manure being the specific food for clover. How long its beneficial influence will endure, experience will hereafter determine. Annual applications of the French and Nova Scotia plaster are considered advisable. The effects of the gypseous earth used by me, are, I think, superior the second year, and far exceed any benefit which I have ever derived from my use of the imported gypsum.

On viewing the prospect before me, I can no longer entertain a doubt that every acre of my fields, (without aid from the stable and farm pen manures,) at the trivial expense of carting and spreading from forty to fifty bushels of gypseous earth per acre, may be made to produce an exuberant growth of white, red, and bird foot clover, and I rely on the experience of others, as well as on my own, for assurance that wheat sowed on a heavy clover lay will yield an abundant crop; and as I am disposed to think that corn, aided by the stubble of the preceding crop of wheat, as well as the putrid clover, will yield as abundantly after wheat as before it, I would suggest the expediency of changing the present rotation, notwithstanding the alleged objections of the extra labor, and the probable detriment to the young clover. For the former, (admitting the fact,) ample recompense will be derived in the increase of the wheat crop, from the improvement of the soil by guarding the vegetables ploughed in, from the waste which is inevitable from the corn cultivation; and as the preparation of the field may be commenced early in September, and easily completed by the 10th of October,—the harrows drawn both by the horses (then at leisure) and the oxen, will sufficiently cover the sowed wheat by two operations, and complete the seeding in fifteen or twenty days. Of the effects on the young clover plants I am not fully informed. My course will be to sow the seed, (without separation from the chaff,) as I "lay by" corn or give the last tillage. The cover on the seed will protract their vegetation, probably until the foliage of peas planted from the 1st to the 10th June will afford protection from the sun.

The cultivation of field peas has so long engaged the attention of farmers as to create a strong presumption that every valuable property appertaining to them must long since have been ascertained, and

consequently, that farther speculation on their value will be superfluous. But, as there may be others as well as myself, who again and again have derived the benefit, and have not noticed, or if they have, have not systematically availed themselves of that crop for the suppression of weeds, grass, &c. and thereby greatly facilitating their sowing of wheat—to those, perhaps, the following notices may not be altogether unimportant.

A rich mold, abounding with the partridge pea, weeds, &c. was last year cultivated with difficulty, and yielded an abundant crop of corn. Early in June, peas were planted equidistant with the corn, covered with the foot, and no farther labor incurred than a slight hilling when the corn was last worked. In October, the vines were removed, and the land remained quite clean, and in the best possible condition for sowing of wheat, which was completed by a single operation of the harrows after the fluke hoe; and at this time my prospects are entirely satisfactory, and no obstacle either to cutting or gathering up the crop is apprehended. My neighbor, from land of precisely similar description, and immediately adjoining, raised an abundant crop of corn, but planted no peas. In October, the double bar share plough was used; the harrows were necessary to smooth the furrows—and after the wheat was sowed, a second operation with them was required to cover the seed, which I considered less effectual than mine, on the rougher surface left by the fluke hoe. His wheat is obviously and greatly inferior at this time; and so overwhelmingly numerous and luxuriant are the vines of the partridge pea, that I am confident he must resort to the reap hook or grass scythe for the preservation of his crop. But be that as it may, I have no hesitation in assuming that the impediments in cutting and the inevitable loss in gathering up the wheat, will far surpass in value the seed peas and the trifling labor of hoeing them—leaving in favor of my course, without drawback, a heavy amount of the most nutritious food (if fed while green, and alternated with corn) for fattening hogs; and if judiciously attended to (when pulled up for sowing wheat) the vines are eminently valuable food during the winter, for every description of stock.

Before I close this communication, (already much longer than I had contemplated,) I must invite attention to the previous notice on the effect of the growth of the field pea on that of the partridge pea. To allege that the foliage of the former, in the months of August and September, obstructed the vegetation of the latter in the month of October, and onwards through the winter, is obviously inadmissible. To what cause then shall we assign it? I hope hereafter to read in your paper a solution of the inquiry; but in the mean time, I shall remain under the impression that the previous growth of the field pea had gleaned the pasture peculiarly suited for the nourishment of both, and left the partridge pea no resource but to await a future and suitable fecundation of the soil.

A SUBSCRIBER.

IMPROVEMENT OF WORN OUT LAND.—It is said that during the last few years, twenty thousand Swiss and Belgian emigrants have settled upon lands in Virginia and Maryland, which had been supposed to be worn out and almost worthless; but which under their cultivation has been made as *productive as the good lands of the West*; in consequence of which lands have risen in value, and industry has received a new impulse. If the farmers of this state will diligently set about improving their land, by all possible means, those who are most anxious to go to the west will soon be cured of the moving fever; and if the people will make a rail road to carry their produce to market, many of North Carolina's valued sons, who have already gone to seek their fortune in a new country, will be told of scenes of prosperity and happiness that will entice them back again to their own, their native state.—*N. C. Star.*

(From the Petersburg Intelligencer.)

DISEASED WHEAT.

We have exhibited to some of our agricultural friends in this vicinity, the samples of diseased wheat, forwarded by our Nottoway correspondent, and alluded to in the subjoined communication. They concur in opinion that it is affected by what is here termed *the blight*, a malady which heretofore has more frequently prevailed in the vicinity of *salt water* than in the up-country regions. Now, as the clouds during the long rainy spell in May, came principally from the east, is it not probable that they were charged with an unusual proportion of *salinated fluid*, [sic?] which like an epidemic, extending westward, has produced on vegetation phases as new to the eyes of our Nottoway friend, as if, supposing him a physician, he were to meet with that scourge of the Atlantic cities, the *yellow fever*, in his rural practice.

Green Field, Nottoway, June 9, 1833.

Gentlemen,—The present appearance of our wheat crop indicates almost a *total failure*. Notwithstanding the unusual quantity of rain which has fallen within the last month, attended, almost daily, with the temperatures of summer's heat, our wheat crop looked promising until about a week past. A disease has attacked it in the head which will baffle the skill of our most experienced and eminent country doctors. They describe the disease, as first making its visible appearance in the *turning yellow* of the straw on the stalk, then commences a *yellow speck* at the top of the head, continuing downwards, interspersed promiscuously on and through the head, until finally the whole of it assumes one uniform color of yellow fever disease. From the heads, herewith sent you, you will be able to form a better idea of the wheat in its diseased state, than I can describe, as my *botanical* knowledge is not sufficient to describe technically the trunk of the wheat, and all of its component parts, with the beauty of a Barton, or the accuracy of a Linnæus. All diseases, whether animal or vegetable, have their proximate and exciting causes, and I hope some of our intelligent and observing farmers will take the subject into consideration, and be able to give us some information on the wheat. I am informed by my oldest neighbors, that they never have before, seen such a disease in their wheat. I sowed from different kinds, to wit, the white flint, (which I now send you,) the wild goose, the bearded, and the smooth head golden shuck; not with a view, as you might infer, of overstocking the market, but to experiment and to find out which kind seems best adapted to my little farm. The smoother head is less injured. Perhaps this may be owing to its being about a week earlier. In the other three, I can discover no very material difference.

Respectfully, your old friend, and
SUBSCRIBER.

(From the New England Farmer.)

POTATOES AND INDIAN CORN.

MESSRS. EDITORS:

Sir,—I here send you the result of several experiments, which I have made. Several years ago, I planted blue potatoes, late in the season, and as all of those which I considered large enough for seed had been culled out, I planted small ones not more than an inch and a quarter in diameter. When I dug them, they were as large as any I raised. Last spring I planted two rows, side by side, of the red potatoes, one row of the largest size, the other the smallest, which I think proper to plant, perhaps not one-third of the weight of the large ones. When I dug them, I could not tell which were the largest. So I conclude, the reason why small potatoes yield small ones, is owing to putting too much seed in the hills; as a small potato has as many sprouts as a large one. But this I have proved, that the same results do not always arise from the same experiments in different

kinds of potatoes. For several years past, we have wanted early whites, and early red eyes, side by side. If the whites were hilled after the blow, they uniformly produced a large number of small potatoes, and but few of a good size; while hilling had no effect on the red eyes.

I made an experiment in planting Indian corn a few years ago, for my own satisfaction. I planted the hills three and a half feet apart on end of a piece of land, and four feet on the other, with the same kind and quantity of manure: about half the length of the rows was on a stiff heavy soil; the other half a light loamy soil; without weighing, I could not tell which gave the best product.

Note by the Editor of the New England Farmer—By some experiments made by J. Whitlaw, Esq. which are given in detail in the *New England Farmer*, vol. i. page 53, and vol. iv. page 314, that gentleman ascertained that large potatoes were better for seed than small ones, and that large potatoes when cut into quarters will produce more, other things being equal, than when planted whole. Other cultivators assert that the best way is to plant potatoes of at least middling size, cutting off and applying to other uses the butt and top ends of each potato, planting the middle pieces cut into quarters. The reason of this proceeding, is, that the shoots or eyes from the middle part of a potato are commonly larger and stronger than those of either end, and if the whole of a large potato is planted, there are usually too many shoots in a hill, and those shoots are too near each other to afford so great a product as they would if deposited in the soil at due distances.

Mr. Knight, the celebrated English horticulturist, has found, that, "for a late crop, small sets, [seed potatoes] may be used; because the plants of the late varieties always acquire considerable age before they begin to generate tubers, [young potatoes;] but for an early crop; he recommends the largest tubers [seed potatoes] to be planted; and he has found that these not only afford very strong plants, but also, such as readily recover when injured by frost; for being fed by a copious reservoir beneath the soil, a reproduction of vigorous stems and foliage takes place, when those first produced are destroyed by frost or other cause." [*Hort. Trans.* iv. p. 418.]

(From the London Horticultural Register.)

METHOD OF PRESERVING THE LEAVES OF TREES, IN CASHMERE, AS A SUBSTITUTE FOR HAY.

From the manuscript papers of the late Mr. Wm. Moorcroft.—Published in the *Geographical Journal*.

In several mountainous countries, greatly distant from each other, and in which much grass, apparently of a good quality, might be cut for hay, as winter food for cattle, I have observed a preference given to the leaves of certain trees for this purpose:—these were the willow, the mulberry, a variety of elm, and several others, but the first mentioned and the walnut were held to be the best, and considered much more warming and nourishing, than any kind of grass made into hay, especially for sheep. Small branches, after having been cut when in full leaf, and before they begin to lose any of their verdure, are immediately so disposed within the first forks of the tree to which they belong, as to be thereby retained in the form of large hay-cocks. These branches are piled loosely, yet are so engaged amongst themselves as not to be detached by wind, neither do they lose their leaves, nor are the least rotted, or in any other respect damaged, as to their fitness for food.

I am not mistaken in asserting, that the fat is whiter of the mutton of Cashmere, not only than of the mutton of Tibet, but of any other sheep I have seen; but whether this difference be wholly, or in a degree, owing to the sheep being fed on dry leaves, I have not facts enough before me to determine.

This forage, unless where very abundant, is reserv-

ed for the severe part of the winter, when the cattle are driven under the trees, on which the store is suspended; and the dry branches being pulled down, are eaten by them with great avidity. The practice is thus simple, unexpensive, affords a considerable resource in a well timbered or forest farm, and may, perhaps, be worthy of trial, if it prove not injurious to the growth or quality of the timber; on which, I refer to what I have already said, of the management of walnut trees, in Cashmere. The scarcity of natural pasturage, has forced the farmers of Tibet, to cultivate the productions of their soil, as lucerne, &c. merely for the increase of fodder; whereas, in Cashmere, the exuberance of natural productions, the neglect of cultivating them to perfection, the selection of the leaves of forest trees, in preference to the leaves and other parts of grasses, and esculent roots, as turnips, &c. may bring the soundness of the judgment of Cashmere farmers into question, by the farmers of England. My observations on this preference are too limited to be of any practical value; but I am able to aver, that sheep, which had been preserved from dying by the rot, through feeding on dry prangos, fell off in condition greatly, when put upon clean washed turnips, and regained their former state rapidly on reverting to prangos. It appears to me not improbable, that if sheep, when they just begin to show symptoms of rot by *arching their backs*, were put on a diet of dry leaves alone, they would be prevented from dying of this complaint; and I conceive would prove speedily curative; also, in the case of the oscaris worm, and rustling in the windpipe of lambs, fed on rank aftermath in the beginning of a winter, following a wet autumn. The arching of the line of the back, perhaps, produced by an attempt, to relieve the irritation occasioned by vigorous activity of the small fluke worms, which have only just entered the gall-ducts, is a symptom I have never heard noticed by shepherds; but, according to my own observation, is the first which indicates their presence, in the beginning of winter. When grass is also stored here for winter fodder, it is twisted into thick ropes, immediately after being cut; and in this state, hung across the upper branches of trees. Without other preparation for hay, it thus keeps free from rotteness, and generally even from moldiness, notwithstanding the great quantity of rain and snow that falls in this country. Grass thus dried, is generally given to the flock in a morning, and the leaves in the afternoon or evening; but the latter are most depended upon for fattening. Oil-cakes, made of linseed, walnut-kernels, mustard seed, along with the seed of cotton, are employed for this purpose, and the flags or leaves of sedge.

I. T.

HORTICULTURE.

(From the London Horticultural Register.)

ON THE CULTURE OF RHUEARB,

WITH SOME ACCOUNT OF ITS HISTORY AND INTRODUCTION INTO THIS COUNTRY.

BY JOSEPH PAXTON, F. L. S. & C.

HISTORY—The first species of rhubarb cultivated in this country, was the *Rhœum raphaniticum*; it is a native of Asia; but by whom it was introduced is unknown. The ancient Greeks called the root of commerce "*Rhabarbarum*," because it grew plentifully on the banks of the river Rha, (Volga,) in Russia. The Greeks, however, of more modern times, changed its name to "*Barbâricum*," because it was brought to Barbary for sale. The species so much in use at that time, has till lately been generally believed to be the *R. palmatum*; but Mr. David Don has satisfactorily proved it to be the *R. australe* of Mr. Don's "*Flora Nepalensis*," and the *R. emodi* of Dr. Wallich. It is, however, very probable, that the roots of various species are used, as the bark of various species of *Cinchona* is collected as the true bark. By

what means, or to whom mankind is indebted, for the discovery of the medicinal quality of the roots, is totally unknown; it is, however, probable, that its virtues were appreciated by the ancient physicians: for Dioscorides, physician to Antony and Cleopatra, wrote on its qualities; in his work on Botany and Medicine, published just before the Christian Era, where he recommends it against weakness of the stomach, diseases of the liver, &c. &c. Galen also, another Greek author, who wrote on medicine about a century afterwards, strongly recommends it for diseases of the liver. Paulus Aegineta, who is said to have been the first man that practised midwifery, appears to have first used rhubarb as an opening medicine. The roots were brought from China, where Michael Boyne, in his "Flora Sinensis," published at Vienna, in 1656, says the plant is a native, and grows in great abundance. It was introduced from thence by Tartary to Aleppo, Damascus, and Alexandria, and thence reached Vienna. It was not known to Europe, till 1535, when the Chinese brought the roots for sale to the city of Goa in India. Valmont Beaumare states, that some soldiers in the army of Charles the V. brought it to Spain from Africa about the same time. This does not appear unlikely, for the dreadful disease, which the followers of Columbus brought from America into Spain, spread with such fearful rapidity, that it became indispensable to adopt measures to stop its violence; it seems therefore probable, this drug was introduced as a remedy; for Girellasso de la Vega, who died in the year 1536, mentions rhubarb as a sovereign cure, for the evil of the newly discovered world.

The Portuguese were the first who brought rhubarb by sea from Canton; but the Dutch soon obtained a part of this trade. In 1597, Gerard mentions, that himself and others had it growing in their gardens, exclusively for use in medicine; and relates a curious anecdote, relative to its use in case of an ague: he says, "I learned a notable experiment of one John Bennet, a Chirurgion, of Maidstone, in Kent; a man as slenderly learned as myself, which hee practised upon a butcher's boie of the same towne. Being desired to cure the foresaid ladde of an ague, which didde grievously vexee him, hee promised him a medicine, and for want of one for thee presente, hee tooke out of his garden three or four leaues of the plante of rhubarbe, which myselte had among other simples given him, which he stamped and strained with a draught of ale, and gave it thee ladde to drinke; it wrought extremely downwarde and upwarde within one hower after, and never ceased untill night: In the ende, the strengthe of the boie overcame the force of the physicke, it gaue over working, and the ladde loste his ague."

Although in the present day, we set great value on the medicinal virtues of this root; yet the principal reason of its cultivation in our gardens, is for the stalks, which are served up in creams, made into tarts, &c. and medical men have all recommended them as amongst the most cooling and wholesome tarts sent to table. We shall not, however, venture to lay down rules for making them, lest our ignorance in the art of cookery, should expose us to the ridicule or displeasure of our countrywomen, which we feel no disposition to run the risk of encountering. We may, however, without fear of contradiction, venture to say, that if the stalks be cut into squares, put in single layers on a pan, and placed in an oven of a moderate heat for about twelve hours, and afterwards put into wide mouthed bottles, with a fifth or sixth part of brown sugar, then covered down with bladder, and occasionally shook for the first fortnight, they make a most excellent preserve.

Rhubarb cultivated in this country, is found to equal for medicinal purposes, that of foreign growth. The palmate leaved was first planted in this country in 1763, and the "London Society of Arts" in 1792 awarded a gold medal to Sir Wm. Fordyce, for raising 300 plants of this species from seeds, in the preced-

ing year. In 1793 it was awarded to Mr. Thomas Jones. In 1794, Mr. Wm. Hayward, of Oxfordshire, received it for propagating rhubarb by offsets taken from the crowns of large plants instead of seeds; and in the same year another was awarded to Mr. Ball, for his method of preserving the roots for use in medicine. Dr. Tirruegel, of Stockholm, states that no roots should be taken up till they have been planted ten years, and that they should be taken out of the ground in winter, before the frosts set in, or early in the spring, and immediately cut in pieces, and carefully barked; they should then be spread upon a table for three or four days, and be frequently turned, that the juice may thicken or condense within the roots. After this process, make a hole in each piece, and put a thread through it; by which let them hang separately, either within doors or in some sheltered situation.

All medical men acknowledge two virtues in rhubarb, that of evacuating bilious humors, and that of fortifying by its astringency the fibres of the stomach and intestines. Lord Bacon remarks, "that rhubarb has manifestly in it, parts of contrary operations; parts that purge, and parts that bind the body, and the first lie looser, and the latter lie deeper; so that if you infuse rhubarb for an hour, and crush it well, it will purge better, and bind the body less after the purging, than if it stood 24 hours." The principle in which the active property exists, is supposed to be a peculiar chemical substance called rhabarbarin.

SPECIES AND VARIETIES.—These have now become rather numerous, but the sorts generally cultivated for tarts, &c. are the following:

1 Wilmot's	4 Elford	7 Gigantie
2 Cox's	5 Hybrid	8 Rhapontic
3 Judd's	6 Buck's	9 Palmate-leaved

Of these Wilmot's, and the gigantie, may be considered decidedly the best; the former being a most excellent force, and the latter grows to an amazing large size without rankness. The palmate-leaved is held up by many as amongst the best for tarts. A. T. Thompson, Esq. M. D. remarks in the Gardener's Magazine, that he has tried the leaf-stalks of almost every species of rhubarb cultivated in Great Britain, and none, in his opinion, are equal to the palmatum; he judges they are more succulent, less fibrous, and contain a much larger supply of rheumatic acid, than those of any other species. Others again are decidedly opposite in their judgment, and complain of its strong medicinal taste, and its dry and wiry leaf-stalks. Now, according to our ideas, both these opinions are perfectly correct; if the roots are planted in strong land, and an exposed situation, the stalks in general are both dry and wiry; if on a very wet bottom in any kind of soil, they have a strong rank acid, but if they are planted in light rich soil in a north or northwest border, their stalks will be found to equal, if not surpass those of the hybridum or rhaponticum.

CULTURE AND PROPAGATION.—All the sorts may be propagated, either by seeds or dividing the roots; the former is the best mode, making by far the finest plants, although in many cases division answers extremely well; care must always be taken to retain a good bud on the crown of each section, and to plant them on good ground, well trenched and manured. It is usual with many gardeners to blanch rhubarb early in the season, which decidedly improves the flavor and appearance, and the stalks requires less sugar to make them palatable, than when exposed to the open air; this may be accomplished by large sea-cale pots, either with or without dung, but if this blanching be done out of the natural season of growth, it comes under the denomination of forcing. To accomplish this properly with little expense and trouble, has led gardeners to adopt many methods. One of the first practised, was placing large pots or handglasses over the roots, and covering them with a good thickness of hot dung, after the manner of forcing sea-cale. Although great crops may be obtained this way, the stalks are

very liable to be much broken by growing against the sides or tops of the pots; to remedy this evil Mr. Judd, of Edmonton, covered his bed with open frame work, around, and on which he placed the dung. On this system it grew very fine, and required much less attention than with pots or glasses. Another method is to take the roots up carefully, and plant them in a fluid mushroom shed, either in a bed of tan, or in pots and boxes filled with light soil, or tan, and allowed a temperature of 45 to 55 or 60 degrees. Tan is preferable to soil, because it receives the water more freely when given to the roots, and Mr. Knight has satisfactorily shown that the roots of all perennial herbaceous plants, contain within themselves, all the organizable matter, necessary for the formation of the leaves, and therefore require little or no soil, but only heat and water for their development. After the forcing season the roots are divided and planted on a north border, and the strongest selected for forcing again the following season. This method we believe is practised at Elford, Kirkley Hall, Pinkie House, Scotland, and many other places. We have found the system of forcing in mushroom sheds to produce large crops, of an excellent quality; and with some exceptions, it may be reckoned one of the best methods in use. We have observed, however, that where much fermentation is going on, with new beds, the color of the stalks have been materially injured, and the flavor nothing near so good as when grown under other circumstances. Others again take up old roots of four or five years' standing, and plant them in large pots of rich mold, as thick as the roots can be placed in each pot; these pots are taken either to a peach-house, green-house, pine pit, or any other place where they can have a good heat, but experience has taught us that old roots when forced, never produce stalks so fine as young roots under similar treatment. Another method practised at Holly-Bush Hall, near Lichfield, is found very successful, particularly with the strong growing sorts; it is true a very large quantity of dung is required to give a sufficient heat in severe weather, but where it can be accomplished it answers extremely well. The young roots are permanently planted two feet apart, in beds three feet wide, with alleys betwixt them two feet wide, and one and a half feet deep. In the autumn, after the leaves are off, fork the beds over, to the depth of four inches, and break the soil small with a rake head, then place a sea-cale pot over each root, and cover the soil in the inside with dry sand six inches thick; this done fill up the trenches with dung from the stables, well shaken together, and carry it up one foot three inches above the beds, then cover the beds with dry littery straw, to the height of one foot three inches above the tops of the pots. The sides of the beds should be built up with bricks, and pigeon-holed.

The system of culture we would recommend, is one that we have practised ourselves with the greatest success; and first we shall give a short detail of our method of

SOWING THE SEED.—About the end of February, or beginning of March, make up a bed of stable dung, about three feet high at the back, and two feet six inches at the front; when well beaten down with the fork, and nicely levelled off, set on a frame of the size required, and lay on the bed, about nine inches thickness of good light rich mold, mixed with a third of good rotten dung; beat these ingredients well together, and when the surface is level, scatter the seeds broadcast, and cover them about half an inch thick, with the same soil broken fine; then put on the glasses, and in about three weeks the plants will be up. As soon as they begin to appear, give abundance of air, and continue to increase it, so that in April the glasses may be taken off altogether; they will, however, require protection from frosts at night, until they are ready to plant out in the open ground, which will be in May.

PLANTING OUT.—If it is intended to plant out for permanent use, select a quarter of good rich soil, and

trench it at least three feet deep, adding a good supply of well rotted dung; be careful, however, in trenching, not to bury all the top spit of soil in the bottom of the trench, but reserve it for the roots to be planted in, for they will thrive much better in it, than in that taken up so far from the surface. Then plant the roots in rows six feet apart, and four feet from root to root in the rows, for the smaller growing sorts, as Wilnotts, &c. and six feet from root to root for the gigantic and other strong growing kinds. Or if planted on Dr. Bevan's system, stated Vol. I, page 456, they will grow very fine. None of the stalks should be gathered the first or second years, but in the third season they may be used as required. Cut off all the flower stalks as soon as they begin to shew flower, except such as may be left to collect seed from, which should always be the finest. Never gather the stalks to excess late in the summer, for if this be not attended to, they will so far degenerate as to throw up the following season a complete wood of spindling, stringy stalks, scarcely fit for use; whereas, if treated properly, they will continue to produce abundantly for many years.

GENERAL CULTURE.—All the culture required after planting out, is to keep them free from weeds during summer, and fork in a good coat of rotten dung every spring; the crowns should also be covered with a portion of half rotted dung, to preserve them from being injured by frost in winter.

PLANTING OUT FOR FORCING.—Take the plants from the hot bed where they were sown, and plant them in rows eighteen inches apart every way, on ground previously well-dunged and trenched two feet deep. Stir the soil about them occasionally during summer to encourage their growth, and by the time they are two years old, the roots will be very fine, and at that age best calculated to force.

MODE OF FORCING.—The best mode of forcing, and one attended with the least trouble, is to place a small frame of one or two lights in a peach-house, stove, or forcing pit of any kind, and having put in a sufficiency of old bark, take up a quantity of roots without breaking them, and plunge them in the bark as thick as they can be put together, until the frame is filled; then cover them down with wooden covers, or the glasses belonging to the frame will do, providing mats be thrown over to exclude the light. If they become dry, water them as often as they require it; and in about a fortnight the stalks will be ready for use. When the first half of the frame has begun to shoot up, fill the other part after the same manner; and when it has grown a little, remove the roots first put in, and fill up with a fresh supply, and continue to do so until the forcing season is over: the roots forced may be either thrown away, or planted; but we would not advise to force them again, as young two years old plants are far better.

Those persons who have no forcing-houses, may have rhubarb something earlier, by placing sea cake pots with loose tops over the roots without dung; and when the stalks get to the top of one pot, take off the lid, and place another pot upon it: this will allow them to grow to a great length, without danger of breaking.

(From the New York Farmer.)

VISIT TO THE LONNEAN BOTANIC GARDEN OF FLUSHING.

On the 10th ult. we took steamboat up the East river to the rural village of Flushing, where is the well known garden of Messrs. W. Prince & Sons.

The first subject to which we would invite the attention of our readers is the collection of Dahlias, comprising above six hundred varieties, three hundred of which have just been received from European collections. Among those the most novel and rare are a number of striped varieties, and one of deep crimson hue, with a white border. One bed contains nine hundred and thirty-six plants. These with an equal

number along the borders, will present, when in full flower, a blaze of beauty probably never surpassed.

There were pointed out to us four varieties of the Judas Tree, *Cercis*, in flower—the European red and white, and the American red and deep crimson; the latter highly interesting, found wild in Maryland, and transferred to the garden by inoculation.

A magnolia grove, containing above sixty large trees of various species, producing flowers and seeds in abundance, afforded a sight of this pride of American forests not elsewhere seen in this part of our country. It has often been remarked that this grove presents its greatest display of bloom at the period of the birth of Linnaeus, the 21st of May, thus seeming to honor the day that gave birth to the father of botany. A lofty tree of the *M. cordata*, or yellow flowering magnolia, was resplendently in bloom. Of this last, Messrs. Prince have two distinct varieties, one of which originated with them from seed. This species produces flowers twice during the season, in May and August. Of the *Magnolia conspicua*, we were shown a tree ten feet high. The *M. obovata* was in its prime, as well as the *M. gracilis* and *pyramidalis*: the purple and cream-colored blossoms of the former present a striking and beautiful contrast to those of the other species. The varieties of the *M. grandiflora*, one of which has double flowers, were equally admirable. The white purple tinged flowers of the *M. soulangeana* had just disappeared. We were pleased to learn that all these varieties of the magnolia stand our winters without the least protection, as was evinced by their vigorous appearance in one of the most exposed situations in the garden.

A large number of the *Wistaria consequana* attracted attention by their splendid floral attire. It is a hardy climber, and supposed capable of standing the winters of Quebec.

A large plot of Azaleas, containing upwards of fifty varieties, presented blossoms of every hue. Among them were the yellow and the orange, and one of double flesh-colored blossoms. In addition to these were rare Chinese Azaleas. The scarlet *Cydonia japonica* was splendidly decked with flowers. Not less gay was the double variety, blush or white flowering. The fruit of the first is small, but that of the last is of considerable size, and possesses a delightful and powerful fragrance, making odorous preserves. Along the main avenue is a number of trees of the Scotch *Ran*, or mountain ash, and near one of them is quite a lofty weeping birch, transplanted originally from its native highlands, overshadowing a seat suited for the perusal of Scotland's romances and poems. A purple leaved beech attracted our attention by the feuilletmort hue of its foliage, giving the casual observer an impression that it was in its last stage of existence.

The roses, amounting to seven hundred varieties, are arranged in large plots or beds, and numbered according to the catalogue. Among them is the yellow musk cluster. Specimen plants of the China roses are planted in separate beds. Of this class are one hundred and sixty varieties, thirty of which are of the latest importation. We were surprised to find the *Kerria* (formerly *Corchorus*) *japonica* so perfectly hardy and resplendent with flower. The Irish yew is distinguished for its erect position, and the deep green of its foliage—a beautiful plant. The Messrs. Prince have near one hundred plants of the *Hamiltania oleifera* or oil nut.

Among the trees which should be in every situation, where animation as it were is to be given to the landscape scene, the Silver Abeel tree should be found. The upper surface of the leaves being green, and the under side white, their very quivering in the gentle zephyr enlivens the eye. There were three species of the snow-drop tree, with their pure white blooms in wreath. The variegated or striped leaved hollies are interesting from the diversity and beauty of their foliage. The leaves of some are covered with prickles that occasion them to be called hedgehog holly.

It was satisfactory to us to find the following trees and shrubs perfectly hardy and acclimated. Three varieties of the Chinese *calycanthus*, the white, the yellow, and the grandiflora, the two former in an open situation, and the latter in a southern exposure—the *Buxes balearica* or *Minorca boxtree*—the spreading and upright *cyprus tree*—the *Pistachia vera*, or true pistachia nut—the *Potinia serrulata* of China—the *Rubus rosafolius*, or double rose flowering bramble—the *Ilex cassine*—the *Lagerstremia indica*, in a southern exposure.

We noticed that the branches of the *Shepherdia elegans* or Buffalo berry tree had been cut off, and on inquiry, found that the plant being a male, they had been carried to some female trees in another part of the garden, to fertilize them. A hedge of the Chinese arbor vitae was particularly beautiful. Several thousand young plants were in growing for the same purpose.

The plot containing the collection of pæonies is extensive, containing 2500 plants of near fifty varieties. The *Pæonia moutan* is one of the most magnificent of flowers, of which Messrs. P. have several varieties, some of them seedlings. They also have about 150 plants from the seeds of the *Pæonia whitelet*, impregnated with the *humei*, and *P. fragrans*. These last are not yet in flower.

A fine specimen of the weeping beech with its peculiar and graceful curve of branches arrested our attention, also the *Fagus cristata*, or crested beech.

In the herbaceous department the species are planted in beds, and arranged alphabetically. This we consider very convenient, both to the proprietors and to visitors and purchasers. In a large collection of violets the *Viola grandiflora* was conspicuous. There are at least a dozen new seedlings of *Aquilegia canadensis*.

Among the collection of *Pinus* we remarked the *P. pinea*, or stone pine, a tree recommended, as our readers will recollect, by Commodore Porter, for the excellence of its fruit.

The Messrs. Prince have bestowed much attention to the grape. They have quite a number of varieties from seed obtained by an admixture of the pollen of many varieties. It is their opinion that it is from seedlings that we must expect to obtain varieties of foreign vines, that will answer as well in our climate as our native grapes.

We observed a number of bee-hives, one of Mrs. Griffith's, and the others of the common construction. The bees in the latter had been all destroyed by the miller, while those in the former were in a thriving condition.

The garden of the Messrs. Prince being a commercial one, it cannot be expected that much attention will be given to picturesque effect. The dwelling of Wm. R. Prince, however, which is connected with the garden, is admirably located for display of taste. Mr. P. has by no means disregarded improvements. He appears rather desirous of crowding into his ornamental grounds specimens of all the beautiful plants contained in the commercial garden, than to illustrate the principles of correct taste in landscape gardening. The out-buildings on the whole premises are with few exceptions very old, and mostly unpainted, and consequently give to the premises a forlorn aspect.

CAMELLIAS.—The Chevalier Soulangue Bodin says, the most essential point in cultivating the camellia is that of not putting it into too large a pot—that this plant succeeds, "far better in a good free-working mold, fine in its texture, and rather sandy," than in bog-earth. This soil is different from that recommended by Mr. Thomas Hogg, wherein he says the most suitable soil is "a free or open black bog earth, well mixed with about one-third of yellow loam." The article of the Chevalier Bodin contains many details, which we should deem excellent.

[New York Farmer.]

RURAL ECONOMY.

(From the Genesee Farmer.)
FEEDING HORSES.

The Quarterly Journal of Agriculture, vol. 2, contains an interesting article on the most economical manner of feeding horses. It will be seen from the extract lately published from Mr. Dick, veterinary surgeon at Edinburgh, that food must be reduced to a pulaceous mass before it can benefit the animal to which it is given, and that bruising, grinding, or cooking very greatly assists the digestive process. The same considerations indicate the propriety of cutting the straw and hay which is fed, and of mixing it with the grain, roots or other feed. The advantages of this mode consist not only in enabling the animal to perform its labor with more ease, but in economizing the food, a great portion of which voided where abundantly fed in the ordinary mode, without having imparted its nutritious properties to the animal. The latter advantage extends to other animals, as the cow, hog, &c. At the milk establishment of Mr. Smith near Baltimore, eighty cows are kept upon cut and cooked food, with great economy of expense. On visiting some years ago, the establishment of Col. Jacques, at Charlestown, Mass., I observed piles of cut hay and straw, mixed with cut roots, bran and water, prepared for his cattle, and was told there was found to be a great saving in preparing their food in this way. Upon our canals and rail roads, where great numbers of horses are employed, a saving of twenty-five per cent. would constitute a large sum in the course of a year. If I mistake not, the cases I am about to cite, will demonstrate the practicability of doing this, and of enabling the teams to perform their labor with more ease than they do now.

Messrs. Hanbury and Freeman, Spitalfields, keep eighty-two horses. The animals receive all their food in the manger, no hay ever being put in the rack. They are kept in excellent health, condition and appearance, upon the following daily rations: 18lbs. cut hay and straw, the latter being one-eighth, 14lbs. bruised oats and one lb. bruised beans, making in all 33lbs. food per diem. The beans are discontinued in summer on account of their heating quality, and an equal addition made to the oats. The mass is blended ere it is fed. Half a pound of salt is given weekly to each horse, one moiety Saturday night, and the other Sunday morning, and operates as a gentle purge.

Mr. Higgins, of London, keeps three hundred heavy cart horses. No hay is fed in the rack. It is all cut down with straw, into lengths not exceeding the fourth of an inch. The oats, barley and beans are always coarsely ground and added to the hay and straw. The hay and straw (equal parts of each) are given to the larger horses at the rate of 19lbs. and to the small ones of 14lbs. per diem—the other materials make up the daily allowance to 40lbs. to the larger, and 30lbs. to the small horses. An ounce of salt is daily mixed up with each ration, except in winter. The quantity remains unaltered through the year; though barley or oats are substituted for beans in warm weather.

Dr. Sully, has for twenty years successfully pursued the practice of feeding 30lbs mixed food to his horses. From the great labor they have to undergo, says the Doctor, being accustomed to travel eight miles an hour, have no secure place, and yet few cattle are in better condition. He objects to racks; because if these are filled, horses are apt to eat too much, thus overloading their stomachs; so that when in this full distended state, they are taken out of the stable and put to work, their wind will be endangered. The rack also, he thinks, occasions great waste of provender. It is the doctor's opinion, that a horse with a full rack of hay will consume and spoil 30lbs. a day; but that when it is cut down, and mixed with a

due proportion of cut straw and bruised or ground grain, ten pounds is enough. The Doctor has his food prepared and mixed in a loft; a box is allotted to each horse, from which a wooden pipe leads to the manger, with a cover at the top, removeable at pleasure. To prevent the horse throwing out his feed from the manger strips are nailed across it twelve inches apart.

Doctor Sully has four classes of food, as indicated below. Of these he thinks that containing the potatoes is to be preferred. Indian corn would be a good substitute for beans and peas, and the Swedish turnip for the potatoes.

	1st Class.	2d Class.	3d Class.	4th Class.
1. Farinaceous substances, consisting of bruised or ground beans, peas, wheat barley or oats, - - - -	5	6	10	5
2. Bran, fine or coarse, - - - -				7
3. Boiled or steamed potatoes, mashed in a tub with a wooden bruiser, - -	5	5		
4. Fresh grains, (boiled barley.) - -	6			
5. Hay cut down into chaff, - - -	7	8	10	8
6. Straw cut down into chaff, - - -	7	10	10	8
7. Malt dust or ground oil cake, - -		2		2
With 2 oz. of salt for each class, -	30	20	20	20

"As the horse advances in age, his teeth gradually lose their perpendicular position, and become less fitted for grinding the hard food, which the nature of his work and his artificial situation in stables, renders it necessary for him to receive. His mastication is rendered imperfect, and the grain, when given him unbruised and unground, is often swallowed entire.—And as the saliva and gastric juice of the stomach are held to be the solvents of the food, and as more perfect mastication must allow these to act with more effect upon it, a more perfect digestion, we may believe, is induced by giving the grain in a bruised or ground state, and by the cutting down of the hay and straw. Thus, must not only the practice be conducive to the health of the horse, but it must produce a great saving of the food. To persons requiring constant and steady work for their horses, the advantages of the practice are very obvious. The carrier, with his horse provender weighed, mixed, put into a bag, and carried with him, can feed and refresh his horse at all times and places. The same observation applies to the farmer. By means of provender so prepared his horses soon fill themselves, and thus have time to lie down, sleep and rest."

No grain is given to horses in Switzerland without its due proportion of cut hay and straw. The hay cutting machine is in general use, for the cow as well as the horse.

If we pass into Germany, we observe the same, or perhaps greater attention to the food of the horse.—To all the grain he receives, a certain portion of cut hay and straw is added, and the practice is not uncommon for the Swiss and German horse-man when on a journey, to feed his stud with coarse brown bread.

B.

(From the Genesee Farmer.)

LAND DITCHING.

MESSRS. EDITORS.

Having read an article in your paper [see Am. Far. vol. 15, page 75] on the subject of draining, permit me to suggest what I am convinced to be an improvement on that operation, as far as regards such spots of grounds as are surrounded by higher grounds.

It is what the English farmers call *land ditching*. This work is performed in nearly the same manner as the writer of said article indicates; with this difference only, that the ditch to be cut may be as narrow, and on both sides as steep, as the convenience of the

operator with the spade will admit, and when he can dig no deeper, a kind of hoe called the scoop, is to be had recourse to; the blade of which, instead of being flat, has its sides turned up so that it is three or four inches wide and eight or nine inches at least in length, with which, standing astride the ditch, the loose earth is scraped up and thrown out, and by doing which the ditch may also be rendered deeper if necessary. When the drain, which requires only three or four inches width at the bottom is thus made, hemlock brush is to be thrown into it, which, when made somewhat compact by ramming it down, must be about half a foot thick; then the earth which was dug out is thrown upon it and the ditch entirely filled up; taking care on the lowest parts of the ground, where the drain of course is shallow, to give it a sufficient coat of earth for the plough to go through without drawing out the brush.

By this practice less digging is required, the necessity of occasionally clearing out the open drain is obviated, no surface of ground is lost, and the plough can go over these land ditches in all directions; the land will at all seasons be properly dry, and after some years when the brush is decomposed, a vein is gradually formed for the water to pass to the lower grounds in the same manner as it does to the source of a well. I have never heard that any hollow spot of ground once land ditched, has ever needed any other operation for keeping it dry.

Perhaps I ought to add, that at the end of the land ditch, whether it issues into an open ditch, brook, or other outlet, some sods of grass or flat stones must be piled up to prevent the earth from caving in, and choking up this very useful drain.

Yours, very truly,

A HOLLANDER.

MISCELLANEOUS.

WILD PIGEONS.

The annexed article affords curious information respecting the peculiar habits of the *wild pigeons* of this country. It is taken from Silliman's Journal for April last, for which periodical it was furnished by S. P. Hildreth.

The most remarkable characteristic of these birds is their associating together, both in their migrations and also during the period of incubation, in such prodigious numbers as almost to surpass belief; and which has no parallel among any other of the feathered tribes, on the face of the earth, with which naturalists are acquainted.

These migrations appear to be undertaken rather in quest of food, than merely to avoid the cold of the climate, since we find them lingering in the northern regions around Hudson's bay, as late as December, and since their appearance is so casual and irregular sometimes not visiting certain districts for several years in any considerable numbers, while at other times they are innumerable. I have witnessed these migrations in the Genesee country—often in Pennsylvania, and also in various parts of Virginia, with amazement; but all that I had seen of them were mere straggling parties, when compared with the congregated millions which I have since beheld in our western forests, in the state of Ohio, Kentucky, and the Indiana territory. These fertile and extensive regions abound with the nutritious beech nut which constitutes the chief food of the pigeon. In season when these nuts are abundant, corresponding multitudes of pigeons may be confidently expected. It some time happens that having consumed the whole produce of the beech trees in an extensive district, they discover another at the distance perhaps of sixty or eighty miles to which they regularly repair every morning and return as regularly in the course of the course of the day, or in the evening, to their place of general rendezvous, or as it is usually called, the roosting place. The roosting places are always in the woods, and sometimes occupy a large extent of

forest. When they have frequented one of these places for some time, the appearance it exhibits is surprising. The tender grass and underwood are destroyed, the surface is strewn with large limbs of trees broken down by the weight of the birds clustering one above another; and the trees themselves for thousands of acres, killed as completely as if girdled with an axe. The marks of this desolation remain for many years on the spot; and numerous places could be pointed out where for several years after, scarce a single vegetable made its appearance.

When these roosts are first discovered the inhabitants for a considerable distance visit them in the night, with guns, clubs, pots of sulphur, and various other engines of destruction. In a few hours they fill many sacks, and load their horses with them.—By the Indians a pigeon roost or breeding place, is considered an important source of national profit and dependence for the season; and all their active ingenuity is exercised on the occasion. The breeding place differs from the former in its greater extent. In the western states above mentioned, these are generally in beech woods, and often extend in nearly a straight line across the country for a great way.—Not far from Shelbyville, in the state of Kentucky, about five years ago, there was one of these breeding places, which stretched through the woods in nearly a north and south direction; was several miles in breadth, and was said to be upwards of forty miles in extent. In this tract almost every tree was furnished with nests, wherever the branches would accommodate them.—The pigeons made their appearance there about the tenth of April, and left it altogether with their young before the twenty-fifth of May.

As soon as the young were fully grown, before they left the nest, numerous parties of the inhabitants, from all parts of the adjacent country, came with wagons, axes, beds, and cooking utensils, many of them accompanied by the greater part of their families, and encamped for several days at this immense nursery. Several of them informed me, that the noise in the woods was so great as to terrify their horses, and it was difficult for one person to hear another speak without bawling in his ear. The ground was strewn with broken limbs of trees, eggs and squab pigeons, which had been precipitated from above, and on which herds of hogs were fattening.—Hawks, buzzards and eagles, were sailing about in great numbers, and seizing the squabs from their nests at pleasure; while from twenty feet upwards to the tops of the trees, the views through the woods presented a perpetual tumult of crowding and fluttering pigeons, their wings roaring like thunder, mingled with the frequent crash of falling timber; for now the axe men were at work cutting down the trees that seemed to be most crowded with nests and contrived to fall them in such a manner, that in their descent they might bring down several others; by which means the falling of one large tree sometimes produced two hundred squabs, little inferior in size to the old ones, and almost one mass of fat. On some single trees upwards of one hundred nests were found, each containing one young one only, a circumstance in the history of this bird not generally known to naturalists. It was dangerous to walk under these flying and fluttering millions from the frequent fall of large branches broken down by the weight of the multitudes above, and which in their descent often destroyed numbers of the birds themselves.

I had left the public road to visit the remains of the breeding place near Shelbyville, and was traversing the woods with my gun, on my way to Frankfort, when about one o'clock the pigeons which I had observed flying the greater part of the morning northerly, began to return in such immense numbers as I never before had witnessed. Coming to an opening by the side of a creek called the Benson, where I had a more uninterrupted view, I was astonished at their appearance.—They were flying with great steadiness and rapidity, at a height beyond gun-shot,

in several strata deep, and so close together that could shot have reached them, one discharge could not have failed of bringing down several individuals. From right to left, far as the eye could reach, the breadth of this vast procession extended, seeming every where equally crowded. Curious to determine how long this appearance would continue, I took out my watch to note the time and set down to observe them. It was then half past one. I sat for more than an hour, but instead of a diminution of this prodigious procession, it seemed rather to increase both in number and rapidity and anxious to reach Frankfort before night, I rose and went on. About four o'clock in the afternoon I crossed the Kentucky river at the town of Frankfort, at which time the living torrent above my head seemed as numerous and extensive as ever.

(From the Newbern Spectator.)

LOUISIANA.

A gentleman of Newbern, N. C. has favored us with the following most interesting extract of a letter which he lately received from his friend in Louisiana. The writer is a gentleman of high respectability, who, previous to his removal, in 1818, was a merchant in Plymouth, in this state. As our own state is hopelessly, and apparently forever, doomed to feel the paralyzing effects of inaction and sloth, we consider it our duty to lay before our readers all the information which we can acquire that may have a tendency to better the condition of such of them as are wasting their energies unprofitably, and desire a change. Of the productiveness of Louisiana we have heard much; but this is the most minute and satisfactory statement that we have seen. The cotton produced there is known to be the best upland in the world, and is now worth 14 cents a pound. Taking then his estimate, eight bales, or 3200 pounds to a hand, which is the result of experiment, the gross amount is \$448; and as the cost of cultivation, transportation, &c. cannot be much greater than with us, we may safely calculate the net proceeds of the labor of one hand at about \$350. Taking the maximum produce of which he speaks, a hand would clear \$450. When we take into consideration the astonishing fertility of the land, the price, though far above the value of our lands, cannot be considered high. The Arpent, if it be the same as that of France, as we presume it is, is 512.605, or nearly 5 6 of the American or statute acre. A wealthy and intelligent planter from Red river is now in this place, who confirms the statements of the writer, and gives accounts of Louisiana still more favorable.

Red river, Louisiana, May 9, 1833.

Dear Sir,—I have just received your letter dated the 12th March, expressive of your wish for me to write you in relation to the health of this country, its navigation, the price of land, if easily cleared, and the practicability of procuring it with improvements, the price and hire of negroes, the product of each hand, and finally, to contrast our lands here with those of Mississippi, and advise you as a friend, &c. &c.—which requests I will proceed to answer with pleasure, and as fully as I am capable.

The chief of the land cultivated in my section is alluvial, and consequently unhealthy, we have however, a good deal of pinewoods with creeks and springs of excellent water, which are repaired to, when contiguous, for summer residence, by many of the planters. Indeed I know some whose plantations are fully twenty miles from the nearest pinewoods, who resort to them in the summer and fall seasons, with their white family, entrusting their slaves to the management of white overseers, whom they visit once a week or fortnight, as occasion requires. I am as I conceive more fortunately situated in that respect than many of my friends. I am permanently settled on the pinewoods, four miles from my plantation, which I visit four or five days every week, if good

weather, and return in the evening. This gives me plenty of exercise on horseback. Were I differently situated, I could not put near so high a value on the country as I do. As regards our navigation, or facility in getting our produce to New Orleans, or our supplies from thence, much depends on our location. Those having plantations on Red river, where steam boats ply eight months in the year, and sometimes longer, below the falls, are best situated, while those on the creeks, as I am, are obliged to haul, or wait the rise of water to boat it.

The value and hire of negroes here I cannot speak of with much accuracy. The law of this state prohibits, at present, the introduction of that species of property, except for our own use: they cannot be sold or hired in any manner whatever, until years after their introduction, nor is it at all common to hire out slaves, the property of minors; they are generally sold, at public sale, with all the other property of the minor's estates, unless provided against by the will of their parents. The price of land has varied considerably since I first came to the country in 1818, when it was high. It has since been at about half the price of that time, but latterly it has advanced again, and I conceive is now as high, if not higher, than at any time since my residence here, and probably on the rise still. In 1819, I bought what may be termed woodland, at 27½ dollars per arpent, payable about one-third cash, and the balance one and two years. In 1827, I bought as good land at 12½ dollars per arpent, the payments about the same, and now such lands would, I apprehend, be held at 20 to 30 dollars per arpent.

As you will have inferred in perusing this letter thus far, it is very common to see land, as well as all other species of property of which planters here are possessed, sold at their death, and if not for debt, the most usual credits given may be stated at one, two and three years, on land. I attended the sale of 480 arpents of land some eight or nine miles from me, on 1st February—it had probably 200 arpents in cultivation, and was sold at one two and three years credit, for a division among the heirs, and brought 16,100 dollars.

Our land here is generally heavy timbered, and consequently very laborious to clear. It is, however, very productive in cotton, and of long last. In N. Carolina, I know many tracts that may be cleared and worn out ere a tract here could be freed of its timber. The product of a hand here in cotton, our chief selling staple, varies materially in different years, and with planters; some years are much more favorable to the culture of cotton than others, and some men are much more pushing than others. In 1830, the best cotton year I have experienced, I find some planters who assure me of their having made ten or more bales, of 400 lbs. to the hand. That however, is more than I have yet realized, and I would say that a bale to the acre, and eight bales to every effective picker, ought to satisfy any reasonable man. For mercantile business, I have long lost all fondness and have therefore no participation in it, and am unable to give you the information on that subject which you desire. I can say, however, that in Alexandria, 20 miles from me, a great many goods are sold, and I imagine at considerable advance, and doubt not that a profitable business might be done by one having the means of laying in his supplies in New York.

With the land of Mississippi I am not well enough acquainted to contrast it with ours here. Suffice it to say, that those of Red river and its contiguous streams, to wit: Bayou Rapide, Bayou Robert, and Bayou Beuff, I consider more productive in cotton than any other I have met with.

In conclusion, I will give you the same advice I have for years given those of my Carolina friends, (who called for it,) having a wish to better their situation!—Come and examine the country yourself, lest after having removed to it you or your family may dislike it. This will not cost much money or loss of

time, and both may be well expended for your children, should you become a grower of cotton. The sugar and cotton growing states you know have an influence on, and greatly serve to keep up the value of slaves in your state, and without saying what is the value of that species of property here, I will venture to say it is more than will cost to bring it to Louisiana.

TURNIP SEED.

For sale the following kinds of Turnip Seed, of the very first quality, at \$1 per pound.

EARLY WHITE DUTCH.

GARDEN STONE.

WHITE FLAT. GREEN ROUND.

RED ROUND OR RED TOP.

WHITE NORFOLK. WHITE TANKARD.

YELLOW ABERDEEN. RUTA BAGA.

And, as usual, a complete assortment of GARDEN SEEDS generally.

I. I. HITCHCOCK,

American Farmer Establishment.

BUCK WHEAT.

A few bushels of very superior quality for seed, for sale at the American Farmer Establishment, at \$1.25 per bushel.

I. I. HITCHCOCK.

N. B. Half a bushel is required to seed an acre.

LINNEAN BOTANIC GARDEN AND NURSERIES, Flushing, near New York.

WILLIAM PRINCE & SONS announce to all the proprietors of Nurseries, and to those who propose to establish new Nurseries, that they will furnish articles desired at a liberal discount, and at a credit that will afford ample time for profitable reimbursement. We wish also to make known to all vendors of Seeds, or to those who desire to undertake such business, that we will furnish every variety of Vegetable, Field and Flower Seeds in quantities, at very low rates and a liberal credit. The seeds possess the advantage of being raised under our own observation, or, when imported, of being tested to our satisfaction.

The assortment of Turnip Seeds alone consists of 27 varieties, including Dale's New Hybrid, the Yellow Altringham, and all other new and choice varieties. In the Catalogue of Seeds will be found many entirely new and very choice varieties, which have never before been offered to the public. The accuracy and vitality of the Seeds furnished by us are expressly guaranteed.

Bulbous Flower Roots, Dahlias, &c., which are easily transported, and generally vended in a dry state at the Nurseries and Seed Stores, can be supplied to any extent, and at rates that will afford a large profit to the vendor.

Every person already engaged, or who desires to engage in the sale of the above articles, will, on application, receive all the information, requisite to the object in view, and such an establishment ought to exist in every town in the union.

The New Catalogues, with reduced prices and extensive additions to every department will be forwarded to all applicants, and the present period is particularly eligible for forming arrangements in anticipation of the fall business.

N. B. It is desired that the applications be made direct per mail.

JACKS AND JENNY FOR SALE.

The celebrated Jack DON CARLOS and two of his offspring (a young Jack and Jenny) are offered for sale.

Don Carlos was imported from the Island of Majorca, in 1820. He is now nearly sixteen years old, (in the prime of life,) is 52 and a half inches high, stout built and in full vigor, his color is black with white muzzle and belly. He is exceedingly docile and gentle. Price \$200.

Also,—A young JACK, a son of Don Carlos, 4 years old, 43 inches high, well made, stout and promising, of same color as his sire—price \$200.

Also,—A full sister of the last, 3 years old, 44 inches high, well made and handsome, color dark iron grey. Price \$100.

If these three animals be taken together they will be sold a great bargain. Apply to

I. I. HITCHCOCK,

Amer. Farmer Establishment.

Ap. 26—ff.

TWO IMPORTED MALTESE JACKS FOR SALE.

These animals were purchased in Malta in June, 1832, for two officers of the U. S. ship Concord, in which they were imported. The selection was left to one of the best judges in the island, who advertised three months previous to purchasing, for the largest and best bred Jacks, without regard to cost—more than one hundred were offered before a choice was made. They are now about three years old, and stand, one 13 $\frac{1}{2}$ and the other 13 $\frac{1}{4}$ hands high, and will yet grow three or four inches: their color is black with fawn nose, eyes and belly. In size, action and vigor, they were believed to be unsurpassed by any Jacks in Malta, and they have been pronounced by good judges, the finest ever brought into the United States. It is deemed unnecessary to say any thing about the superiority of the Malta Jacks; it being well known that they are of the high bred stock of Persia and Arabia.

These animals may be viewed and every information respecting them, may be obtained, by applying to I. I. Hitchcock, American Farmer establishment, Baltimore. The price is \$600 each.

HARVEST TOOLS, WHEAT FANS, &c.

SINCLAIR & MOORE, have in store, and are manufacturing a general assortment of HARVEST TOOLS, among which are

1000 WHEAT FANS, double and single geared.

300 Grain CRADLES, with Scythes complete. This article is made of the best and most durable materials, and will be warranted as such.

50 doz. Grass and Grain SNEATHS.

30 do. Hay and Manure FORKS.

30 do. RAKES and Wooden tined FORKS.

SCYTHES and Sneaths, hung ready for use.

SICKLES, English and American Scythe Stones, Strickles, &c. &c.

Their Stock of CASTINGS, Agricultural Implements, Garden Tools and SEEDS, is as usual full and complete.

Also, just received from Europe, two bales, containing Lucerne and Ray Grass, Cabbage, Radish, Lettuce, and many other valuable SEEDS of last year's growth. From the appearance of this lot of Seed; and the respectability of the establishment from which they were imported, they can with the greatest confidence recommend them.

May 24.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Scythes, Grain Cradles, Scythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street.

Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET—There is no change in the prices of produce, except a trifling advance in Howard street flour, fresh ground and of favorite brand. Grain of all kinds remains as before, with very little doing—the approach of the harvest measurably suspends operations, both with sellers and purchasers.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 1.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for cigars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, '6 00 a 20 00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 340 hds. Md.; 156 hds. Ohio; 25 hds. Ken. and 5 hds. Penn.—total 654 hds.

FLOUR—best white wheat family, \$6.75 a 7.25; super; Howard-street, 5.62 $\frac{1}{2}$ a 5.75; city mills, 5.62 $\frac{1}{2}$ a 5.75—city mills extra 5.57 $\frac{1}{2}$ a —;—CORN MEAL bbl 3 62 $\frac{1}{2}$ —GRAIN, best red wheat, 1.12 a 1.18; white do. 1.25 a 1.31.—CORN, white, 60 a 61, yellow, 62 a 63;—Rye, 65 a 67—OATS, 36 a 38.—BEANS, 75 a 80—PEAS, 65 a 70—CLOVER SEED 8.00 a —TIMOTHY, — a —ORCHARD GRASS 3.00 a —Tall Meadow Oat Grass 2.00 a 2.50—Herd's — a —Lucerne — a 37 $\frac{1}{2}$ lb.—BARLEY—FLAX SEED 1.37 a 1.50—COTTON Va. 11 $\frac{1}{2}$ a 13—Lon. 12 $\frac{1}{2}$ a 14—Alab. 11 $\frac{1}{2}$ a 13—Tenn. 11 a 12 $\frac{1}{2}$; N. Iron, gray pig for foundries per ton 33.00 a —; high pig for forges, per ton, 28.00 a 30.00; bar Sus. per ton, 75.00 a 85.00.—Prime Beef on the hoof, 5.75 a 6.50—Oak wood, 3.00 a 3.25; Hickory, 4.00 a 4.50; Pine, 2.00.

CONTENTS OF THIS NUMBER.

Editorial. Farmers' Register; Dionca Muscipula, Venus' Fly Trap; Valuable Memoranda; Early Tomatoes; Vegetables for Premium—Culture of Turnips—To Destroy the Bee-moth—Extraordinary Ox—Specific Manures, Clover, Field Peas—Improvement of Worn Out Lands—Diseased Wheat—Experiments with Potatoes and Indian Corn—Method of Preserving the Leaves of Trees, in Cashmere, as a Substitute for Hay—On the Culture of Kibbarb, with some Account of its History and Introduction into England, by Joseph Paxton, F. L. S. &c.—Account of a Visit to the Linnean Botanic Garden at Flushing—Culture of Camillias—Experiments in Feeding horses—Land Ditching as practised in Europe—Description of the Roosting Place of the Wild Pigeons in the Western Country—Letter from a Gentleman in Louisiana giving an Account of the Productions and Resources of that Country—Prices Current of Country Produce in the Baltimore Markets Advertisements.

The American Farmer,

Edited by GIDEON B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum: due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged by THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect at THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

5. DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, G. I. Irvine Hitchcock, Baltimore, Md.

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, JULY 5, 1833.

VALUE OF COCOONS—*their quality and preparation for market.* So many inquiries are daily addressed to us for the price of cocoons, the manner of preparing them for market, &c. &c. that we deem it proper to give the information in this way. It is impossible to state the exact value of cocoons except upon inspection. They may appear to the unpracticed eye to be of the first quality, being of the largest size and of the firmest texture, and yet worth nothing for reeling; because, they may be *double*, (spun by two or three worms,) which so interlock their fibres as to render them incapable of being reeled; or they may have been injured in the process of curing, or smothering the insects, which cannot be detected by any one but the reeler, or one skilled in the business. Both these descriptions of cocoons are worthless to the reeler. The same well formed and large cocoons, though free from the above faults, will be more or less valuable according to the manner and degree of curing. For example, a parcel of cocoons of first quality as to size and form, if just cured with the body of the crysalis moist and fresh, will be worth twenty-five per cent. less than a like parcel with the crysalis perfectly dry; because, in the first place there is less weight of silk fibre in the pound of cocoons, and in the second place the moisture of the crysalis renders them extremely liable to mold. All these considerations, therefore, render it impossible for us to say what cocoons are worth. The purchaser must examine them before he can say what he will give for them, and his judgment will be regulated by the proportion of *double*, imperfect, or injured cocoons the parcel may contain, compared with the good sized, well formed, and well cured ones. If the cocoons are of good size, have been well cured, and the crysalis well dried, and if there are no double, imperfect or injured cocoons in them, they will be worth fifty cents a pound; and less in proportion to the number of faulty ones, till the value will be reduced to twenty-five cents a pound—and it would be not worth while for the reeler to trouble himself with any that would not be worth the latter price.

Cocoons of the first quality can only be produced by strict attention to the worms, to the curing, and preparing for market. The little "Treatise on the Culture of Silk," by the Editor of the American Farmer, for sale at this office, price twelve and a half cents, contains all necessary directions on the subject. The worms must be kept supplied with as much food as they will consume, fresh and free from moisture; they must be kept clean, dry, and well aired. When they begin to spin they should have proper mounting frames, and not be crowded for room in forming their cocoons—this is necessary to prevent double cocoons. As soon as the cocoons are finished they should be cured by baking, steaming, or exposure to the sun. In baking them great caution is necessary to avoid scorching them. In steaming, equal caution is necessary to avoid decomposing the fibre—they should not be touched or stirred till they have become dry and cold. In curing them in the sun, care must be taken that they are exposed a sufficient length of time to kill and dry the crysalis. Whatever method of curing is adopted, the cocoons should be exposed to the sun or spread out in a dry airy place to dry perfectly; and they should never be packed up for market or future use till the crysalis shall have been found (by taking several out of them) to be perfectly dry. When they are ready to pack up for market, they should be examined, all faulty ones taken out, and then packed in barrels or boxes, by putting in just as many as the box or barrel will hold by gentle shaking down, but without pressure; a few *cloves* or other pungent aromatic should be put in each barrel or box to prevent mildew; and the box or barrel

conveyed to market with as little agitation as possible. If the cocoons are mashed or much dented, they cannot be reeled.

The greater part of the cocoons that have been offered for sale, were not worth any thing. Probably nine tenths that are raised are so imperfect that the reeler can make nothing of them. The cause of their imperfection may be always traced to the carelessness and inattention of those who attended the worms. If the worms are stinted in their food; if wet or injured leaves have been given them; if they have been crowded on the tables or mounting frames, or disturbed after they began to spin; the cocoons will be more or less imperfect, according to the degree of such bad treatment. The best cocoons are always made by worms that begin to spin, on or before the twenty-eighth day after they were hatched; and they can only be made to do so by giving them a full supply of fresh clean leaves; keeping them clear of litter, not crowded on the tables, and airy. Good cocoons are made by worms that begin to spin on or before the thirty-fifth day; but those that are longer in beginning to spin have been so stunted in food, or so retarded by unfavorable weather, that their cocoons will always be imperfect. Perfect cocoons will generally weigh from the sixteenth to the twentieth of an ounce. We have often had them to weigh the sixteenth of an ounce, and would not call any perfect that did not weigh the twentieth. But, good cocoons when the crysalis is perfectly dry, will often be found to weigh only the twenty-eighth to the thirtieth of an ounce. The degrees of quality of imperfect cocoons are so various, that it is impossible to describe them. If they are soft and flimsy, though of full size, they are to be considered imperfect, according to the degree of softness, and depreciated in value, in the same proportion. If one end is soft, or not perfectly occupied by the fibre, appearing to have a hole in them partially covered or open, they are to be rejected as bad. If they are stained, which is often the case, by the crysalis having passed into the fly state and made an attempt to emerge by discharging a fluid on the inside, before it was killed, they are to be rejected as bad. And, finally, if the worms are sickly, their cocoons will be flabby, and generally small, light and imperfect. A first rate cocoon will weigh the sixteenth of an ounce, be of an oblong oval form, firm texture, and granulated surface; and according to the degree of variance from these qualities will be the imperfection of imperfect cocoons.

INDEPENDENCE.—Why may we not say something about independence as well as others? Are politicians the only independent class of men, or are farmers less benefited by the Declaration of Independence than others? Yet, we do not intend to indite a homily on the great political event the anniversary of which returned yesterday—that event and its anniversary will be remembered while the people of the United States enjoy the liberty asserted by it. But we would avail of the occasion to make a remark or two on the word independence, so much used at the present moment, so little understood, and the sense of which is so little practically felt by mankind. What is the meaning of the word? *Independent!* of whom, and of what? Who in this world, what nation on earth is independent? None—no, not one! The great Lydian monarch, "the richest of mankind," was not independent; neither was the Roman empire. Poor Cræsus could not buy, nor Xerxes conquer it. The truth is there is no such thing as independence. Every man is dependent upon his neighbors, every hour of his life, for something necessary to his comfort, if not to his existence; and every nation is alike dependent upon other nations, for something necessary to its independence! But if comparative independence,—a state in which the least possible dependence on others is required,—be what is meant by this much used word, then who are they that enjoy it? What class of mankind are in the least degree dependent on

others? The tillers of the soil, undoubtedly. They are the most independent of any men on earth; for they have the keys of the store-houses, and none can eat or enjoy any manner of human comfort, but by their permission. Though a wall as high as the clouds were to encircle his farm, and thus shut out the whole world, of what thing necessary to his real comfort, would it deprive the farmer? Nothing but the company and converse of the world, with a few luxuries deleterious to his welfare. The farmer is not only independent of all other men in a high degree, but he has also the highest degree of power over others. But, practically, in what does the farmer show his independence, and where exert his power? Does he not often sacrifice the one, and lend the other to those whose use in their own ambitious designs, satisfying himself with the slavish privilege of looking on and admiring, while he toils and sweats to raise means to pay the expenses of their gorgeous displays? When will the farmers learn to know their rights, and to feel the independence that really belongs to them? When will they learn the immensity of their power? We would not have them *exert* it; but we would be glad to see them understand their own strength—then, and not till then, will they really enjoy independence. We have said we could not wish to see the farmers exert the power with which they are invested, and why? Because, the speedy annihilation of all other classes of society must follow it.—Suppose the farmers of the United States were to organize as a party, and determine on any particular course, where is the profession or party that could oppose them? In such an event, all must succumb to the overwhelming numbers and power of the farmers. We could not desire, therefore, to see this lion aroused to the fury incident to a full knowledge of his power, but we should be glad to see him so far awakened from his lethargy as to enable him, occasionally, to shake the dew from his mane, and the gad flies and gallinippers from his body.

The Newbern Spectator assures the American Farmer that its quotation from Irenæus was *not* intended "to ridicule the statement relative to the produce of Mr. Willis' vine." On reading the certificate in the Farmer the passages in Irenæus recurred to its memory, and it sportively placed them in juxtaposition.

FOREIGN MARKETS.

LIVERPOOL COTTON MARKET.

May 21—This week, so far, the sales have been equally limited, and have not exceeded, in the five days 10,000 bales, which includes 500 Am. for export, and 200 Sea Islands on speculation. Cotton is not freely offered, consequently the extreme prices of last week have been realized. Some purchases have been made in bond, deliverable 1st June, and the sellers have obtained the greater portion of the benefits in the reduction of duty. We quote extreme prices of uplands at 62 to 75-8 a *ld.*—P. S. There is a good attendance of the trade here this morning, who are giving full prices for Cotton, which is not freely offered.

May 22—Rice is flat and lower, 137 casks new Carolina, offered at auction, were bought in at 32s 6d to 33s. 133 hhds Kentucky leaf Tobacco sold at 3d, demand rather limited.

Letters of the 24th state that the demand for Cotton was more extensive, the opening of the Scheldt having given an impulse to the market. Tar and Turpentine rather lower.

LONDON CORN EXCHANGE, May 22.

The arrivals are again, this week, more than equal to the demand, and the trade, consequently, very dull. Wheat was a difficult sale at Monday's prices, whilst barley and oats (for each of which there was a trifling demand) were a shade cheaper.

AGRICULTURE.

SYSTEM OF FARMING.

MR. SMITH: *Penpark, Va. June 12, 1833.*

Dear Sir.—Agreeably to my promise, I have sat down to give you the result of my experience in farming for forty years. I removed from the county of Loudoun, to Albemarle, in the fall of 1799, with but little experience in farming generally, and much less in improving worn out land. At that time the whole face of the country presented a scene of desolation that baffles description—farm after farm had been worn out, and washed and gullied, so that scarcely an acre could be found in a place fit for cultivation. It will be well to observe here, that there is a ridge of red land passing through the counties of Albemarle and Orange, whose soil was of the very best quality, and susceptible of the highest degree of improvement, but which had at the same time been *butchered* by that most horrible mode of culture adopted by the first settlers of this country. The practice then was to clear the land, to put it in tobacco for three or four years in succession, according to the strength of the soil, afterwards in corn and wheat alternately, or corn and oats so long as it was capable of producing any thing. They never ploughed in those days, but simply scratched the ground, and this too, right up and down the steepest hills, instead of horizontally, with those little one horse half share or shovel ploughs, until the whole of the virgin soil was washed and carried off from the ridges into the valleys. This is a very imperfect description of the face of the country at the time of my settlement here; I believe it would not be saying too much, if I were to affirm, that there had not been before that period, one good plough in the county. Col. Thomas Man Randolph, had commenced the horizontal ploughing on his farm; but, for the want of good ploughs, it was along time before he could succeed sufficiently well to induce others to adopt the same plan. Indeed, there were many who, though considered at that time good practical farmers, were disposed to ridicule it for years after Col. Randolph had adopted it. And here, since there has been some little discussion of late in regard to the question, who first introduced this mode of ploughing, I will take the liberty of saying, that there is no person in Albemarle who ever doubted, nor do I myself doubt, that although some considerable improvement may have been made by others since that gentleman adopted it, yet he is entitled to the whole credit of its original introduction, and for which he deserves a monument to his memory.

Suffice it to say, in regard to the condition of the country at the time I speak of, that it wore the most haggard, frightful, poverty-stricken appearance imaginable, never having had upon it either plaster or clover, or, as one might naturally judge from its looks, vegetation of any kind. We had but one alternative in this state of things, either to improve and restore the soil, or to remove to some new and better country; which latter course was the most common—the majority of farmers, after they had impoverished their lands, preferring to leave the improvement of them to others, rather than undertake it themselves. There is here, as in all other places, a great variety of opinions in regard to the best mode of improvement—the manner of ploughing, whether deep or shallow—the time of ploughing—the time and manner of applying manure—questions which must be decided according to circumstances, and not by a single invariable rule. There are some things, however, which may be considered as all important—such as a rotation of crops, a rigid and scrupulous attention to the collection and preservation of all the manure that can be obtained, and great care in ploughing; for good ploughing, in my estimation, is the first step towards the improvement of an exhausted farm.

I will now proceed to give you a more particular account, both of my practice and success in the busi-

ness of reclaiming exhausted land. The farm, which it is my lot to possess, lies near the town of Charlottesville, has been obtained by small purchases at different times, and now contains from two to three thousand acres. This tract of land is acknowledged by all to have been more completely galled and butchered than any other of the same size in this neighborhood. My practice has always been to plough as deep as possible, and according to my constant direction to my ploughmen (*men*, not *boys*, for I do not suffer boys to plough) is not to be afraid of ploughing too deep, provided the horses can pull the plough. For some years past I have made use of four horses in flushing the land, but from the great disadvantage they have labored under, in consequence of the very undulating surface of my farm, sometimes ploughing too deep, and at others too shallow—as for instance, in ascending a hill, the lead horses would draw the plough out of the ground, while in descending, they would plunge it so deep as to be unable to pull it at all—I have been compelled to use three horses at least; which is as small a force as any farmer should think of applying; notwithstanding even this mode has its objections, principally arising from the danger thereto, that the horses when turning, unless great care be taken, will cork themselves. Mine have been frequently injured in this way. The plough which I prefer to all others, is the bar share, called here the London bar share, which was first introduced into this neighborhood by myself. I do not mean to say, that there are not other ploughs equally good, but this in the end is the cheapest. For notwithstanding it costs something more than the M. Crumck, which is our next best plough, though not sufficiently strong for three horses in our rough soil, yet it will last three times as long. The bar share is now in much greater demand than any other, but unfortunately for us, there are very few to be had, not having any person in the county who understands the manner of making it. This plough not only does the best work, but does its work with more ease to man and horse than any other with which I am acquainted.

And here, permit me to say a word in relation to the question of deep or shallow ploughing, which I have seen recently discussed in the Farmer. My opinion, which is founded entirely upon experience, is decidedly in favor of the superior utility and value of deep ploughing. For about twenty years, I have been ploughing as deep as I could on the farm where I now reside, without having in a single instance injured the crop; and more than this, I have, in the mean time, restored the land from the most extreme state of poverty to that of at least good farming land; indeed, a great deal of it is as rich as is necessary for a wheat crop. The rotation of my crops has been once in corn, and twice in wheat, rye or oats in five years, giving two full years in five for clover, and in the mean time dressing the land twice with plaster, (or at least rolling all my seed of every description in plaster,) with from one bushel to one and a half the acre. By putting this quantity upon the clover, the spring after it is sown, ensures me a crop on almost all my land, sufficiently large to mow. Every acre of my farm not under cultivation is kept in clover. With respect to the production and the application of manure, I have never pursued any uniform course, but have been frequently making experiments. I was once inclined to believe, that no other way was right, but to haul it out and plough it under as soon as possible, not allowing the sun to shine on it more than could be avoided, and so strong had been the force of habit and of education, that I pursued this course for several years, without ever supposing for a moment that any other course was or could be right. But, as a large portion of my land had been so completely exhausted, and galled and ribbed by rains and bad treatment, that to put upon it manure in its rotten state would be worse than folly, I came to the conclusion, that it would be a better mode to cover all its deep sores with thick plasters of unrotted straw, carried directly from the machine. In

order to save labor and time, this straw was carried out as a return load while engaged in threshing the wheat; for our practice in this county differs from the common practice in many other places, especially at the north, in not stacking our wheat, but in taking it directly from the field to the machine. This mode has been forced upon us by the apprehension, that if it were allowed to remain for a long time unthreshed, say till the month of August, it would be destroyed, or at least materially injured by the weevil. But, to the point—I am fully of the opinion, that this description of land cannot be so well improved in any other way as in the one just mentioned, for by the time the coat of straw is completely rotten the land will possess sufficient life and strength to manufacture or produce its own covering. A few other experiments, which I have made in regard to manure, may be worthy your attention. In the fall of 1828, I commenced following my land, and carrying out my manure at the same time. The manure was spread and ploughed in with my large ploughs, but as I had a considerable quantity to haul, and some distance to haul it, I did not finish until some time after I had sowed my crop. I made, therefore, four different experiments—a part of the manure was ploughed in with the large ploughs—a part spread on the broken up land and harrowed in—a part spread on the surface after the wheat was sowed—and a part spread upon the snow, according to the practice which, as I am told, exists in Pennsylvania. The first experiment succeeded the best, and contributed most to the permanent improvement of the land—the second did not vary much in its results from the first—the third produced the greatest crop the first year—the fourth did not succeed at all, as it killed a great portion of the wheat.

In regard to such a valuable article as that of manure, it may be well to remark, that very few of us make more than half of what we really might make; and, after all, suffer a great deal of what we do make to be wasted, for the want of a little care. All that even our best farmers in Albemarle have attempted to do, is to collect all their corn stalks in some convenient place, to be used as litter for the farm pen during the winter, which, together with a few leaves from the woods, and a little refuse from the farm, is converted into manure. This is about all that we have done yet.

Before I conclude this letter I wish to add another remark, in regard to the subject of deep and shallow ploughing. This seems to be the more necessary, not only because public discussion is now awake, but because I have a fact to communicate, about which I am greatly astonished that so little has been said, and which may afford us some light. It is this—if you plough your land ever so deep, so much so as to hide every particle of the soil, by the next season it will have all returned to the surface without any subsequent deep ploughing—a fact, which I do hope some of your more experienced correspondents will explain for me. In whatever way it may be explained, it does seem to me to speak most powerfully in favor of deep, instead of shallow ploughing. In my view it is reduced to a certainty, that just so deep as the plough goes, just so deep the soil goes and no deeper. The question then comes to this, which is preferable a deep or shallow soil? about which there can be no dispute. When I first commenced the practice of deep ploughing on my farm, the people who passed along the road would stop and inquire, with great earnestness, whether I was not afraid of ruining my land. After expressing my conviction of its utility, they would most generally reply, that it might do for your wheat, but it would not for corn. But I can only say, that I have found it best for every crop. I would pursue this subject further, but I find my paper giving out. If what I have advanced will aid the interests of agriculture in any respect, I shall be happy. Yours, respectfully, and sincerely,

JOHN H. CRAVEN.

P. S. Our harvest has just commenced. In this

county, while we shall have more than an average crop of straw, we shall not have a half a crop of grain, and even that will be more different than any that I have ever seen, being infested with every thing that is bad—rot, scab, smut and rust. J. H. C.

(From the Genesee Farmer.)

RUTA BAGA.

To those who wish to try the Swedish turnip, and desire information as to its culture, we submit the following considerations, the result of some years' successful experience with this root.

The soil best adapted to the Swedish turnip is one of loose texture and dry, inclining to sand, gravel or loam. It should be rich, well pulverized and clean. A clover ley, covered with yard manure previous to its being ploughed under, is to be preferred.

The preparation for the crop consists in one perfect ploughing, a ley, a faithful harrowing, and the roller may be applied between the ploughing and harrowing with benefit.

The season for sowing is from the 25th June, to the 5th July. [In Maryland from the middle to the last of August is found the best season.] A cutting of early clover may be first taken off the ground.

The best method of sowing is with the drill barrow, an implement which costs ten or twelve dollars, and which comes in use for other purposes, in drills two and a half feet apart. With this a man will put in four or five acres a day. The crop may also be sown broadcast, or drilled in with a line and hoe, though the operation is more tedious, and, when sown broadcast, the expense of cleaning and thinning materially increased.

The quantity of seed requisite for the acre is one pound—cost seventy-five cents to one dollar—though if well drilled, half this quantity will suffice.

The after culture consists in thinning the plants and keeping the crop free from weeds. The plants should be thinned to eight or ten inches, as soon as they show the second or third pair of leaves, and it is important to have the first weeding performed early, as this not only benefits the crop, but saves subsequent labor.

The implement best adapted to the turnip culture are the cultivator, or horse hoe, and turnip hand hoe. The first is passed between the drills as soon as the plants show their second pair of leaves, and may be repeated at intervals with little expense and manifest advantage. It destroys the weeds, if applied in time, except on a strip of two or three inches where the plants grow, pulverizes the surface, and renders the soil permeable to atmospheric and solar influence. The operation of cleaning is finished with the hand hoe, the cutting part of which may be likened to the blade of a thin case knife, the two extremities of which are drawn out, turned up, united, and form the shank to attach the hoe to the handle. The advantages of this hoe are, that it does not gather the dirt and weeds, and may be drawn along the drills as far as the arms extend without being raised, and across the drill, between the plants to be retained, and almost wholly supersedes hand weeding. Two cleanings with the hoe generally suffice.

Gathering the crop is performed with the greatest economy of labor, by drawing the turnips by hand, and laying them separately across the drills, the roots of two adjoining rows towards each other, and then with a heavy knife, bill hook or like implement, strike off the tops with a blow as they lay, which is managed with great expedition. The roots are first gathered, and taken to the pit or cellar, and the tops, which are abundant, are then raked into small piles, and taken to the yard for the farm stock as they are wanted.

To secure for winter, pits are made in the field, upon dry ground, two and a half feet broad, and as long as may be convenient, and of two to four feet in depth. These are filled, and the roots piled above the surface, in a roof-like form, till they terminate in

a ridge. A slight covering of straw is then given, and the whole covered with earth, two feet or more in depth. A salutary precaution is then to make holes, with a bar, at intervals of three or four feet, upon the ridge, through the covering, that the rarified air which will be generated may escape. This may be partially closed with a wispy straw. Another precaution is to cover the mound with a coat of yard manure early in December, the better to exclude the frost. [In Maryland it is only necessary to gather the roots for convenience of feeding, while the ground is frozen, as they stand out perfectly.]

The product, under good management and on a suitable soil, is seldom less than six hundred bushels per acre, and often much more, of roots, besides a heavy burthen of tops, of which neat cattle are very fond.

Use.—This turnip is far more nutritious than the common turnip, keeps much longer, and is greedily devoured, cooked or raw, by horses, cows, sheep and hogs; and is withal a very excellent vegetable for the table, particularly from January to June. We are still feeding to cows and oxen (May 23) of the crop of last year. Our cows have eaten them daily for nine weeks, and yet the turnip taste has not been perceptible either in their milk or butter—the cows having daily access to salt. To the sheep his bandman this root will be found peculiarly serviceable, if fed to his flock in winter and spring.

Of all root crops, if we except the common turnip, this is the least exhausting, occupies the ground the shortest time, is cultivated with the least expense, is saved with the least care, and we think makes the greatest return in food for animals. B.

(From the Maine Farmer.)

ON THE SMUT IN WHEAT AND THE CAUSE OF IT.
MR. HOLMES: *Winthrop, April 17, 1833.*

A late number of the Maine Farmer, contains an article from the Albany Argus signed H. It is a well written article, "on the smut in wheat and the cause of it." [See Am. Far. vol. xiii, page 412.] In that article the writer discards the generally received opinion respecting the cause of smut in wheat—advances the novel hypothesis that smut is produced by a bug which he names the smut bug; and relates his experiments and observations to substantiate his theory, but omits giving what is of much more vital importance to the farmer, viz. a remedy for smut.

In this communication I intend to state what I suppose to be the cause of smut in wheat—give the results of some little experiments, by way of proving what I know to be a complete preventive, and make some observations touching H's theory, which may tend in some measure to refute it. I have supposed that pure wheat like various other productions of the earth, might degenerate and produce smut, or, that owing to some casualty, such as cold, heat, wet or disease it might fail to blossom, and produce smut.—These causes acting separately or conjointly may be the first moving cause of smut, while smut itself, being an efficient agent in propagating its kind, becomes the continuing cause.

When I was a little fellow, I observed my father washing wheat to sow. I asked him why he did this? He replied, "to rid it of smut." I observed that after he had skimmed off all the kernels of smut from the first water, he washed it thoroughly in the second and third waters.—I asked him why he washed it so much after he had taken off all the kernels of smut. He replied, "that particles of smut adhering to the wheat will cause it to produce smut." Young as I was, I had imbibed the idea that smut germinated, and was too incredulous to relinquish my notion of the subject. To satisfy myself I took a number of kernels of smut rubbed them in my hand and added a handful of the washed wheat. On one side of the field where the pure wheat was sowed

with small stones (boy like) I walked in a few feet of ground and sowed my smut wheat thereon. In wheat harvest I had a fine crop of the bane of wheat, while the wheat which grew contiguous was entirely free from smut. I then felt that inexperience should not be too confident—that experience is "the best school-master," and from that time became an advocate for washing wheat to sow.

My father had ever foliowed that practice and had ever raised pure wheat, although he had frequently bought impure seed. Indeed he had never seen a head of smut for a long time, and entertained the idea that it grew in the same head with the wheat, and when he first saw the smut head his curiosity was aroused.

In the spring of 1831, I contracted with a gentleman farmer to take charge of his farm. I could not conveniently obtain any other than smutty wheat for seed. My employer was not slow to condemn this "mess of smut." I told him perhaps I could learn him "a thing or two" concerning smut. I washed this wheat thoroughly, sowed it and raised from it excellent pure wheat. From the result of the first experiment it appears reasonable to infer that smut does not germinate, but, by adhering to the wheat, contaminates or diseases its roots and blade, imparts to them a vitiating principle which prevents the head from blossoming and consequently produces blighting of the kernel. This is abundantly proved as there was no kernel of smut in the seed sown, and as there was nothing but pulverized smut in it, the smut must have been produced by some process similar to that above described.—The result of the second experiment satisfactorily proves that if smutty seed be washed smut will be prevented.

From the result of both these experiments we see the fallacy of H's supposition that smut is produced by a bug. In the first case the smut was rubbed hard in my hand and reduced to a powder. Had there been eggs or grubs, as H states, they must have been mashed and destroyed.—But even supposing they had been preserved and had hatched into smut bugs, why did they not overleap their scanty domain and commit their lawless depredations upon the circumjacent territory? In the second case the wheat was washed by a brook in the wheat field and the smut left remaining. Had the eggs in this smut hatched, the bugs would have gone in quest of their natural food and would have showed their strong partiality for the wheat nigh the brook. But nothing of this was discovered. H's experiments prove that smut is the ailment of the bug, that it riots upon it and generates in it and nothing farther. If this is allowed to be a proof that the bug is the cause of smut, from analogy he might reason that the woodchuck is the cause of clover, because he inhabits the clover and feeds luxuriantly upon it. H states, that wheat, sowed on land manured with the manure from the yard, into which the straw and chaff of smutty wheat had been thrown the year previous, produced abundance of smut. This is perfectly reconcilable with my position. The wheat caught the contagion from the smut in the manure as is fairly proved to be the fact in my first experiment.

Now, Mr Editor, allow me, through the medium of your paper, in plain farmer style, to address myself to my brother farmers. Gentlemen, I have not the temerity to suppose that I can instruct the experienced. I would modestly appear before my superiors, not supposing that I am originating ideas for the majority of farmers. But as often as I see smutty wheat, or smutty bread upon the table, I am furnished with ocular demonstration, that there are farmers who do not know there is a remedy. In fact the very existence of smut in every considerable quantity, calls for something on this subject, and let this be my apology.

Now if you have smutty seed wheat, just take it and a couple of tubs, a bucket, a sieve, and a quantity of slaked lime, or unleached ashes, to a brook or

pool of warm water. Cold water you would find rather uncomfortable to the hands. Then take off your coat and roll up your sleeves farmer like, put about half a bushel into one of the tubs, fill the tub with water, stir the wheat so that the smut may rise, and skim off the smut from the water. Repeat this operation of stirring and skimming until all the kernels of smut have risen and been skimmed off, and then pour off the water. Wash your wheat in a second and third water, rub it *hard* in your hands so as to detach the particles of smut from the kernel, not do it at the halves by stirring in with a stick as I have seen some do, pour off the water, drain the wheat over the sieve, empty the wheat into the spare tub, add at the rate of four quarts of slaked lime or a peck of unleached ashes to the bushel and your wheat will be ready and fit to be sown. Lime or ashes not only serves as an aliment for the plant but may tend to counteract the influence of smut and absorbs the water from the wheat so that it can be easily sown. Without it wheat would fall in bunches from the sower's hand. Wheat may remain in lime sometime without injury, but it should not remain long in ashes as the alkali tend to destroy the vegetating principle of the grain.

Farmers, follow these directions and our ears will no longer be grated by the dissonant cry of smutty wheat—our eyes no longer behold upon the table the black loaf of *schite* bread, and our nauseated and disordered stomachs no longer furnish indubitable evidence that farmers are heedless and negligent in preparing their seed, and in not furnishing their wives and fair daughters with wholesome, pure and white flour. PLUGH BOY.

HORTICULTURE.

(From the Genesee Farmer.)

LECTURE ON HORTICULTURE

Delivered before the Buffalo Lyceum, in March, 1832.

BY LEWIS F. ALLEN.

It was remarked by the celebrated Dean Swift, that he who caused two blades of grass to grow where but one grew before, should be considered a public benefactor.

If such be the fact, those who have made great improvements in the cultivation of the soil, ought to reap a rich reward of public gratitude; and well would it be for the whole human family, if all wars and contentions could be confined to rival emulation in the peaceful arts, and all their implements of destruction be converted into the plough share and pruning hook. What a delightful scene for the philanthropist! What a field of contemplation for the philosopher and christian! And if ever such happiness be the lot of this world, those who cultivate the soil will be the first to invite, by their peaceful occupation, its blissful era.

The regular course of our studies will this evening present before us the subject of horticulture, or the cultivation of the garden, with its legitimate productions of esculent fruits and vegetables.—For our present purposes, it is not necessary to pass through an examination of the various vegetables which are in common use among us; or into the dissection of their component parts.—Their utility is too well understood to need diffuse remark; and as our present object is to disseminate a correct taste, and more general attention to their cultivation, we proceed at once to our subject.

The cultivation of gardens has partially existed from a remote period in the world; but the art has been brought to its present perfection within the period of a few centuries. For ages after the earth was inhabited, we have no reason to suppose that the cultivation of the ground was in any other than the rudest state; and history, as far as it can be traced, is almost silent on the subject. The authority of holy writ presents the history of our first parents in a gar-

den; but the term is so general, and the word "garden" might so aptly apply to many delightful valleys in the voluptuous climate of Western Asia, that we can have no definite conception of its appearance and productions, as compared with the "gardens" now in cultivation among us. And from the known and gradual improvements in the melioration to domestic uses of the vegetable kingdom; and the exceedingly rude state of the world for many centuries thereafter, we may fairly presume that but little was known of the vegetable world at an earlier date.

The ancient patriarchs, with their numerous families and tribes, led a pastoral life; subsisting chiefly on the milk and flesh of their flocks, and the simplest fruits and vegetables of the earth, which in that luxuriant soil and mild climate flourished in great abundance. As the earth became more populous, and the people assembled themselves into colonies and nations for mutual protection from the assaults of those more powerful or barbarous than themselves; and as subsistence by plunder became more precarious, they resorted to the cultivation of the soil, in common, with directing their attention to the mechanic arts; and as these last improved, the former kept a slow yet regular pace beside them. For many centuries, even after the soil was cultivated for subsistence, the inhabitants were not scattered in sparse settlements over its surface; for so general was the practice of war and depredation, that no safety was found but in congregating the people into towns and cities, which were strongly walled and fortified. They daily went without the walls to cultivate the adjacent fields, or inclosed a sufficient quantity of ground with their habitations to suffice for their more pressing necessities. It would indeed appear that the various and tempting fruits, scattered through the land, should have invited the attention of those people to engage early in their cultivation. But the genius of the universal world seemed wholly bent on the acquisition of power, and the more direct means of its promotion; and their labors in time of peace, owing, perhaps, to their numerous collections into cities, were more directed to architecture, sculpture and painting, than to the improvement of the soil.

The people of ancient Greece, while rearing those immense structures of art, whose very ruins challenge the admiration of the world, were ignorant of the simplest classification of vegetable nature. And the more refined Romans, whose profound literature and correct taste in the finer arts, stood for centuries without a rival, knew but little of the rich and abundant treasures of the vegetable world. True, eminent instances of individual inquiry and investigation into vegetable physiology are recorded; but so long as the national taste was pursuing another channel, these inquiries could make but little progress. War, eloquence and the arts, by which to perpetuate their achievements, were the prevailing tastes, of the period in which they live; and the more humble, peaceful, and useful studies of the vegetable world were neglected; and like the mechanic arts had arrived to but a rude state of development, as the world emerged from the dark ages into the more benign and liberal era which first dawned upon its people.

As mankind have become enlightened in science and the arts; as their views have been expended by study and investigation; and as the benign influences of social order and moral virtue have spread over the nations, new discoveries have been rapidly made in the great mine of vegetable nature, and her hidden treasures have brought forth, producing abundantly to the benefit and luxury of man. At the present time, the art of horticulture has become expanded into a science; and what had ever before been deemed by the general world as consigned to the unlearned tiller of the soil, or to the secluded rustic, as a subject too vulgar for philosophical inquiry, has of late received the minutest and long continued investigation from our most enlightened physiologists and natural historians. And to the general student, no

science or study has afforded more peculiar satisfaction. The vast phenomena of vegetable nature, as she gradually unfolds it to the inquiring gaze of her votary, presents continued objects of profound admiration; and things, common as the air we breathe, when examined by the clear light of science, develop such strange and pleasing features, that we silently wonder at our former lack of curiosity.

The natural productions of the earth are exceedingly simple; and it is matter of much doubt whether any considerable portion of the grains, pulses, roots, herbs, and fruits, which are now produced in such endless profusion and variety, were, when first discovered, either palatable or desirable food. Many of the most important grains were hardly a resemblance to their present appearance or value. The wild pea and the bean, as they climbed up the luxuriant wild weeds in their native grounds, were scarcely food for the birds or quadrupeds. The potato, when first discovered in the new world, was a small bulbous root not larger than a filbert; and the sweet potato, one of the richest, most nutritious roots in existence had hardly enough of virtue in its wild state to bring it into notice. The cabbage, with all its fine variety of cauliflower, kale, and broccoli, was hardly larger than the leaf of an ordinary clover. Also, in like unimportant state were our present most esteemed garden vegetables. The plum, the cherry, and the apple, were as we now know them in their native wilds, of little value, and but little removed from the yet humbler fruits which grow around them. The fig, the olive, the orange, and the melon, as they existed in the wild regions of their nativity, had barely attraction sufficient to justify attempts at their improvement. Yet by the judicious cultivation of their several kinds, transplanted into a genial soil, and the ingenious improvement of their natures, they have become eminently subservient to the uses, necessities, and luxuries of the human family.

If it be asked how this great variety and profusion of vegetable nature, that we daily see around us, has sprung into existence while her first productions seemed to be dispensed with so sparing a hand; I answer, it is the result of human ingenuity, aided by a friendly climate, and a generous soil, in developing and maturing their faculties and powers. As the mind became expanded, and began to inquire into the formation and properties of the vegetable life, experiments were commenced; art and ingenuity were put into requisition; accident also contributed much to the discovery; and shrewd, intelligent observation lending its aid, great results were in time wrought out; continual improvements have been made, and our present luxuriant and bountiful productions are the consequence.

Before the art of printing was discovered, the science of vegetable physiology was but little known, and confined principally to the more polished nations of the earth. The Carthaginians were considered in their time as the best cultivators of the soil. Some of the ancient Greek authors wrote treatises on agriculture, and on the cultivation of fruits. Virgil wrote his polished poem entitled the *Georgics*, on the subject of rural economy and improvement; but for the want of correct scientific knowledge in those times, strange mixtures of popular superstition, error, and prejudice were more or less blended in all their writings. And many of these relics of a benighted age, I regret to say, are prevalent at the present period. To allay those prejudices, and correct those errors, and to promote intelligence, is one great object of all our study and investigation; and well would it be for our nation were our whole people guided, on this subject, by the simple voice of experience, and the plain undeviating principles and laws of nature.

We now inquire in what manner have the present great variety of vegetables been multiplied from their original stock? The character of all vegetables, from their close and intimate relation to the different

parts and composition of the soil and atmosphere, are easily susceptible of change. Their reproduction by seeds; transplanted into different soils and climates, together with mechanical or accidental causes, may create a slight difference or modification of their properties or relations. We are to understand that the *genera*, or *species*, of a plant is never altered by cultivation. It is only the character, and the uses it may be susceptible of, that become refined or improved thereby. The crossing, or admixture of the pollen of one vegetable, with the farina of another, is a further and the principal cause of variety in the vegetable world. Seeds of one plant may be sown in the immediate vicinity of another. The productions, or fruits of these plants may be the same as those from which they spring; but if the farina of their flowers be mixed, the seeds of either kind may produce fruits differing from both; or having the blended character of the two. The operation is perfectly easy, and may be readily understood. Every male flower springing from a vegetable, has in its centre, and issuing immediately from the stem, a *stamen*, so called. This *stamen* is covered with *pollen*, which is a fine white, yellow, or brown dust.—This *pollen* being carried by the wind, birds, insects, or the hand of man, and mixed with, or scattered upon, the *farina*, or inner surface of the female, or fruit bearing flower of the same plant, or that of another capable of admixing with it, imparts a share of its character to it, and hence the production of a different variety. In this manner, horticulturists have multiplied many fruits and vegetables to an almost infinite extent. Climate and soil have, however, as before observed, an important bearing on vegetable character; and many fruits and garden vegetables have so great predilection for certain locations, that their flavor becomes immediately changed on removing them to other locations, although the principal characteristics of the soil and atmosphere is, to appearance, nearly the same. When, therefore, we take into consideration the remote period of time that vegetables and fruits have been cultivated; their natural tendency to run into new varieties, and the easy process by which they are multiplied; their great utility in administering to the support, to the convenience, and the luxury of mankind, together with the pleasures arising from their cultivation, it is not surprising that we now see them produced in such endless variety and profusion.

The utility of a well cultivated garden needs no comment. To all who are possessed of ground, and have a family to provide for, it is no less a convenience than a profit. For edible purposes, garden vegetables are invaluable; and are all important to the body for sustenance and health; and the form of obtaining them fresh from the ground where they grow, is an important item in their use. To those who have sufficiency of ground, the want of a garden is altogether inexcusable; and if the cultivation of one be neglected, a proper regard to the health and comfort of their families requires a different practice. Many persons who depend upon their supplies of vegetables and fruits from market gardeners, are not sufficiently careful in selecting them. Vegetables which are green, should, to be healthy and nutritious, be perfectly fresh. Those which are wilted and stale, are unhealthy, and decidedly worse than none. *All succulent plants*, when used green, are in a rapid state of growth and development. Their stalks, leaves, and roots are full of active juices, which have been recently elaborated; and if the sources of life be suddenly checked by plucking them from the earth, and exposure to the air, they soon wilt from a rapid evaporation of their juices, and the process of decomposition immediately begins. They are thus, in many instances, rendered actually injurious. Salads, radishes, asparagus, greens, cucumbers, peas, and many others, may be named. Some are more liable to injury from exposure than others. We will here briefly illustrate this position.

Vegetables consist of, or are made up of carbon, oxygen, hydrogen or water; and occasionally, azote or nitrogen. This last is a most poisonous gas. During the day, when the sun or atmosphere is acting powerfully on vegetable life, oxygen and hydrogen, being the basis of the nutritious and saccharine qualities, is rapidly given off through their numerous pores. The azote or nitrogen remains. Now this is the case with wilted vegetables. The fine, succulent, and nutritious part is decomposed into the atmosphere, and the worthless parts are retained. Some plants so treated are actually poisonous; and all are more or less injured. Those who understand the subject can at once detect them by the taste.

This is one great reason why cholera, dysenteries, and cholies are so prevalent in the months of July, August and September; particularly in large towns and cities; when wilted, stale, and, therefore, worthless vegetables are in continual use; and the markets and shops are filled with miserable unripe fruits, bruised from careless treatment in carrying them to market; for which purpose they are picked from the tree in a green state, and crushed into almost rottenness by jamming, jolting, and packing together in great quantities. All such fruits are positively injurious, in promoting those diseases, and ought in no instance to be used. Good, well ripened fruits are food that we all love. Taken in moderation, they are healthy and in many instances nutritious. They contain in larger or smaller quantities, sugar, acids, mucilage, and sometimes gluten. The various kinds of wood on which they grow, absorb or take up from the soil and atmosphere the different sustaining principles of their fruits, for which they are peculiarly adapted. These properties, while the fruit is in progression, are in a crude imperfect state; and in unequal or *improper* quantities (if we may be allowed the expression.) But as the time of ripening and perfecting the fruit approaches, the various parts of acid, sugar, and mucilage, with their carbon, oxygen, and hydrogen, assume their proper proportions, and the fruit is fully matured. It is now most fit for food, and will remain in that situation longer or shorter according to its kind, till decay commences. It will, therefore, be seen, that unripe fruits, like stale vegetables, are unprofitable as well as unhealthy articles of food.

Fruits seem to have been created for our rational enjoyment; and in a country where they may be so easily reared, we are hardly to be excused if we do not obtain more or less of them. To those who know how easily they may be cultivated, it is matter of surprise at the apathy which exists on the subject. We all run with avidity after the oranges of the tropics, and think them remarkably fine fruit. So they are when plucked in golden ripeness from their native trees; but were the West Indian to view us expatiating on the luxuries of an orange as sold in our markets, he would at once laugh at our ignorance. Those which we purchase are plucked green from the tree; and while on their voyage hither, obtain a sickly, premature ripeness, so that we taste none of the delicious flavor of their native clime. But we may have fruits in our own gardens far preferable to those, with little trouble and expense. The apple and the pear; the plum and the cherry; the different kinds of melon; the smaller fruits and berries, nearly all grow with us in great perfection. Even the peach and acetarine give us a partial share of their delicious qualities; and the vine, with its yellow and purple clusters, is often seen hanging in luxuriant festoons in our gardens. Still with all these facts staring us in the face: and these tempting fruits almost within our reach; we neglect their cultivation, and spend our money for the unripe trash brought from a foreign land and offered in our stores. The poor, unripe, and tasteless Malaga grapes are annually imported into our towns, and sold to our people for three shillings a pound; while those of abundantly better quality and finer flavor can be raised in our own gardens and yards in two years from a naked slip, which any one may

obtain for the asking. It has often occurred to me, that if we lived under the reign of a Roman Emperor, who should happen to take the cultivation of fruit into his consideration, that all those who have opportunity and neglected to cultivate, would be forbidden to eat it, so easy is it to be obtained. Even in our large cities of New-York, Philadelphia and Boston, are large quantities of the finest grapes, and other small fruits, raised in the yards of the dwellings; and I know of many families, who, after supplying themselves, and giving largely to their friends of these delicious fruits, send many dollars worth to market. And shall it be said that we, who have room and to spare, shall neglect a subject so pleasant in its practice, and so easy in its execution? Yet such is the fact. But few, comparatively, among all our town and country people, cultivate the finer fruits; and many are almost deterred from the cultivation of even the few they have, from the uncertainty of rearing them to perfection, and preserving them from the plunder of the licentious, or the importunate begging of their thriftless and neglectful neighbors. For the credit and enjoyment of our people, these things ought not to be. A correct taste for cultivating gardens and fruits should prevail throughout the land; and enough, and to spare, of the choicest bounties of Heaven would be at our command.

Another, and a powerful argument why fruits should be generally cultivated, is the tendency they have to keep us temperate. Lovers of fruit are seldom fond of intoxicating drinks; and were it plenty and cheap in our markets, and throughout the country, its influence in correcting a taste for alcoholic liquors would be most salutary. From the grape, which grows spontaneously in many regions of our country, good wines can be made; and how much better the innocent and palatable liquors of our native vine, than the spurious mixed, poisonous, and intoxicating wines continually imported by our merchants; even with certified, sworn, and sealed labels too, and called cheap, or light wines! Yet in this paltry traffic, are our unsuspecting and credulous population wheedled out of millions annually, as the sacrifice of their gullibility! It does not become the present occasion to look farther into the history of this impoverishing trade; but a slight acquaintance with the important wine countries of Europe, would readily convince us of their incapacity to furnish us with a tithe of the liquor called wine that annually deluges our land.

Another circumstance may be mentioned as not of little consequence to those who are in the habit of cultivating fine fruits and vegetables: it is the exceeding facility by which at particular seasons they obtain friends! Now if the cultivation of these were universal, it is altogether probable that the calls and visits of our friends would be tolerably uniform throughout the year. But when only a few individuals in a village or neighborhood cultivate choice fruits and plants, and that too in any considerable quantity, it is quite amusing to see with what kindness many persons, who previously have been almost perfect strangers, now become their most intimate and particular friends. As the fruit season arrives, they receive a multitude of calls from most obliging acquaintances, who are peculiarly solicitous about the health of their families, and are always happy to drop in and taste their choice fruit; and be on exceedingly intimate terms with them at that particular season of the year. But let that season pass, and the once thronged and hospitable door, where so much *disinterested friendship* has been recently professed, become silent as the Capulet's tomb! I once knew a gentleman who cultivated a large peach and plum garden, which yielded him great abundance, and it cost him hundreds of dollars a year to give them away in receiving genteel visits and tea drinkings during the fruit season, from persons he little knew, and who never cared a fig about him. I have known others too, who were so continually annoyed with the importunity of their neglectful neighbors in begging their fruits, that in

self-defence they were obliged to cut down and cast away, like the barren fig, beautiful trees, to prevent offence by refusing to have their fences destroyed and grounds trodden over, and to suffer the various inconveniences which the presence of their fruit subjected them to. These instances, I am happy to say, are becoming less frequent, and it is with pleasure that they need no personal application within my present knowledge of our neighborhood; and in well bred communities, the right of the cultivator to his productions is as strictly recognized, as that of the merchant to his goods, or the banker to his purse. Public opinion is rapidly correcting these errors, and "it were a consummation devoutly to be wished," that the rich and luxurious fruits of our land should become as plenty and as cheap as our soil and climate are susceptible of producing them.

It does not come within the scope of our present subject to remark upon the several kinds and varieties of vegetables and fruits which may claim a share of our cultivation. Their existence is so common; their various properties and uses are so well known; and the general process of their culture is so well understood by many of our enlightened horticulturists, and so thoroughly laid down in the books which are to be found on the shelves of all our booksellers, that a repetition of the ordinary process of rearing them would be trite and uninteresting. It yet remains, however, for us to remark upon the means to be used, and the benefits that may result from the prosecution of this important branch of our subsistence, convenience and enjoyment.

We have seen that the productions of our gardens are of prime necessity for our culinary purposes; and that by the aid of skill, ingenuity and science, immense improvements have been acquired in their character, and many vegetables, literally worthless in their original growth and locations, have by being transferred into proper soils, and receiving suitable culture, become of primary importance for our use. It becomes then, all who have the prosperity of our great community at heart, to foster a taste for the cultivating and improvement of our gardens, and to bear testimony both by word and deed to their importance. The morals of a people can be very correctly judged, by the appearance of their grounds and gardens. The virtuous man loves to see the bounties of the Almighty blooming and bearing their rich burthens around him. He delights to nurse their tender shoots, and train them up to full and fruitful maturity. How redolent of power! how indicative of wisdom, the formation of the vast vegetable world! and how does the mind glow with admiration, to witness the noble plants of its training, grow on, expanding and developing new features and new virtues through each successive year of their cultivation! Let then, every virtuous mind acquire a taste for an employment so instructive, so useful, and amusing; and let gardening become a part of the employment of all such as have time and opportunity.

As a means of promoting a desire of this kind, may be mentioned the formation and existence of Horticultural societies. These have done infinite good in promoting a correct taste in garden culture; and in all places where there has existed a spirited society, do they greatly excel in horticultural productions. True, numerous excellent gardens may be found where no such associations exist; but by thus producing a community of feeling, and a rivalry in production, a deeper interest is excited; and garden specimens are often elicited to the astonishment of even the most credulous. In all this rivalry and emulation, there need be nothing adverse to the kindest feeling. It is a competition of a high moral tone, and such as has often deeply engaged the loftiest minds. Let it not be supposed that base, a groveling propensities, or weak and diminutive intellects, are to be thus whiled into temporary amusement by associations of this sort. It is a game for deep science; cool, deliberate investigation, and practical skill: a school

for the naturalist, the chemist, and the philosopher; and a study also for the simplest, and most unsophisticated mind. Think you the names of Chilton, and Mitchell; of Quincy, and Lowell, and Story; and Spencer, and Hosack; of Buel, and Le Roy, and a host of other brilliant and reputable names would associate in such societies for purposes unworthy their attention, or genius? Yet these men have unbent their mighty minds from the severe toils of their professions; and relaxed their grant labors to go into honorable and equal competition with the humblest of their fellow citizens; and have felt high gratification on receiving the meek reward, which in justice to their skill, their productions had entitled them. There is something of high moral virtue, of deep-toned patriotism, in the example of our great men thus exerting their influence in promoting a taste among our people for these humble and innocent, yet highly useful and happy employments. To see those whom wealth, and talents, and high character, have rendered conspicuous in our land, meet on equal terms for manly competition with their own gardeners and many of their poor yet respectable neighbors, and offer the labors of their own hands as examples of their vegetable productions; and after receiving the award due their industry, ascend the desk and discourse so richly upon the utility and practical character of their associations, savors much of a benign and happy influence. And such are the results of a cultivated and enlightened taste for horticulture. But for this, how many rich fruits and plants, now blessing with their existence the human family, would still have lingered along, worthless shrubs on the plain, or thriftless weeds in the desert! May we not then with signal benefit fit to ourselves, and advantage to the community around us, imitate such high example? Let the work be commenced. Let those engaged in horticultural labors among us, associate for the purposes of laudable competition and improvement, and the beneficial results of our industry will rapidly evince its utility.

Another important result has emanated from such associations: the publication and dissemination of horticultural papers. Until within a few years past, not a paper of the kind could obtain support in our land. Now, thanks to the enlightened taste and public spirit of our people, several valuable papers of the kind are established through our country. Yet many of these I regret to say, are sustained far beneath their merits; but it may be hoped that their own salutary influence will excite a spirit of inquiry and improvement in the subject, until the art of cultivation shall be brought to full perfection. I can most freely recommend to your attention a publication of the character I have remarked, and with full confidence will name to you the *Genesee Farmer*, published at Rochester; which, so far as it has progressed, has indicated a practical skill, and a promise of utility highly creditable to our state, and honorable to its conductors.

May we not, then, hope that the time is not far distant, when the science of cultivation shall be taught as of primary importance in our schools; when, instead of being consigned to the ignorant and obscure as a subject unworthy minute inquiry to the scholar, or of investigation to the learned, as we have reason to fear it too often has been, its practice may become universal, and its productions widely disseminated—that the most untutored may understand its labors and the most destitute may share its bounties.

COTTON SEED OIL.—A correspondent of the New York Courier gives the following account of this oil:—It is as limped as water, I have seen it burn, and no one can discover a difference between it and the best hard winter strained oil; for machinery, it cannot but be superior to Olive oil, being perfectly free from glutinous particles; as a paint oil it has properties beyond the common Linseed, the oil cake is more nutritious for cattle than Linseed oil cake, and the sediment makes the best of printing ink.

(From the Genesee Farmer.)

EFFECTS OF THE LAST WINTER IN CAYUGA COUNTY, NEW YORK.

Greatfield, 5 mo. 27, 1833.

Although the winter in many respects, was much milder than the preceding, yet several of my shrubs have suffered more severely. A double *Althaea* (*Hibiscus syriacus*) which has stood since 1825, appears to be entirely killed. The holly, though well eased in evergreens, has lost every cat, and several inches of the ends of the branches. Who in the Genesee country has been more successful? I despair of succeeding with this fine tree.

Rhododendron ponticum, and *Syrax glabrum*, though quite as well sheltered as in former years, are entirely destroyed; and *Aralia spinosa*, which in the preceding winter, had only lost a summer's growth, now appears to be killed to the ground, *Filix agnus castus* has fared no better; neither have two varieties of the pomegranate (double and single) also well banded with evergreens. Only a small part of *Periploca graeca* is left alive.

An experiment on *Hydrangea hortensis* was made by a very liberal application of henlock boughs, to ascertain if it could survive without *lying down*; but it is dead to the ground. *Hydrangea quercifolia* is undoubtedly a harderier plant; and its inability to withstand the frost in England, has not been exaggerated, I would ascribe the difference to our hot summers in maturing the wood. It was rather more damaged than in the preceding winter, which may be imputed to a diminished vital energy, in consequence of having blossomed last summer: it was the first time.

On the contrary the Isabella grape which was left on the trellis in the finest condition, though it had nearly perished in the winter of 1831-2. The black Orleans [black cluster?] the only exotic vine which I left uncovered, is but slightly damaged, and will doubtless bear fruit, for the first time under such exposure. Among the shrubs which have wintered better than in former years. I may mention *Bignoni radicans*, *B. gra diflora*, *Kerr a japonica*, *Coronilla emerula*, *Jasminum humile*, and *Lonicera flexuosa*. The last has new branches several feet from the ground, which has not happened before in five years.

The warm weather in the first month caused the blossom buds of the peach and of the apricot to start; yet although the thermometer was afterwards down nearly to zero, the damage was less than I anticipated. About two thirds of the apricots were killed, but a smaller proportion of the peaches. Notwithstanding there is young fruit in abundance on the trees.

D. T.

(From the New England Farmer.)

LARGE APPLE TREE.

There is at present standing in Duxbury, county of Plymouth, an apple tree remarkable for its age, size, and fruitfulness. This tree is over forty feet in height, branches very wide spreading and large, the circumference of the trunk eight inches from the ground is sixteen feet; at four feet from the ground it spreads into two branches, one of which is nine feet in circumference. These again spread, the larger into three, the smaller into two branches, each of which equals an ordinary apple tree in size. It covers with its branches a space of ground thirty-one paces in diameter. In its most fertile days, it bore seventy-six bushels of apples for winter use, and not many years since, the fruit made ten barrels of cider, besides thirty bushels for the cellar. Its ascertained age is near one hundred years. It still is quite productive and sound, the upper and lower branches bear alternately. The fruit is of a pleasant sour, rather tender, but keeps well all winter.

(From the Genesee Farmer.)

TO DESTROY THE TURNIP FLY AND OTHER INSECTS IN HOT BEDS.MESSRS. EDITORS: *Potter, May 25, 1833.*

I think your correspondent, a Practical Gardener, does not recommend the very best expedient for destroying the turnip fly and other insects in hot beds. Because, firstly, I think his expedient is very tedious. Secondly, it is very uncertain. Thirdly, if a part escape they will inevitably destroy the young plants.

I deem the following much better adapted to the object: Take a tea spoonful of sulphur or brimstone reduced to a coarse powder—put it on a small piece of paper and lay it in the hot bed—then light a piece of brown paper and lay it burning on the sulphur—it will soon set the sulphur on fire, then put down the sash close. The burning sulphur will destroy all the oxygen in the frame and pervade every part of it, destroying every living thing within it. After two or three minutes the sash may be raised and the sulphuric fumes blown out and no insects will be left to do mischief.

Such is the conviction derived from practice and theory. Yours, &c. R. M. W.

(From the Virginia Farmer.)

WILD SILKWORM.

Extract from a letter to the secretary of the Hamilton county Agricultural Society.

"I will now furnish you with an interesting extract from a letter of my friend in Paris, Doct. L. Deslongchamps, and from his pamphlet or memoir on the *wild silkworm*. I have I believe, already mentioned to you, that when I shall be able to publish the third part of my work on silk, I intend to abridge that pamphlet as an appendix to it—because the importance of the subject of wild silkworms, the value of their silk, and the great facility with which they can be raised and are already propagated in China, renders it desirable to diffuse all matters of knowledge and experience respecting them, that we can obtain. But for the present I give you only the following extract from said letter, with a drawing of a suspended cocoon, which, however, will give but an imperfect idea of this kind of wonderful work.

"North American people whose extensive lands produce so many analogous vegetables and insects to those of China, may possibly find the same kind of wild silkworms and cocoons as those of Bengal and of the neighboring districts. I invite you to call up the attention of agriculturists and naturalists, to caterpillars and moths, or butterflies, of unusual size and colors; specimens of the present were brought by M. Lamarepiquet, who has travelled and remained more than seven years in different parts of those countries. The cocoons herein exemplified are as big as small hens' eggs, and unlike them are elliptically rounded at the ends, excepting a little protuberance at the part in which the pedicel is affixed, they are from 24 to 22 lines long, and 14 in diameter; this suspending appendage is cylindrical and one-twelfth of an inch thick, somewhat bent at its lower end, blackish, and made up of clues glued together by a gummy resinous fluid, at its base or loop it forms a perfect ring of 3 or 4 lines around any secondary or subsidiary branch below which the lower fabric is to be formed and protected, when this cord is terminated in a proper length its clues or fibres divide in circular and diverging directions to form the outside and glazed layer of the cocoon, much like the net work spun by the caterpillar one over the other, these differ, there are, from our ordinary silk cocoons, which are copiously furnished with a kind of tow, different from silk, which has to be removed before they are reeled.

"These cocoons are rich in silk, for they weight without the crystal, 64 grains a piece, being much more than our ordinary cocoons, which at best weigh

but 6 or 8 grams. From this extraordinary inclosure, the metamorphosed insect issues in the same mode as our silk moth, performing during a short period of existence its natural and last acts of laying up, or fecundating its eggs. This wild caterpillar grows to the size of 4 inches in length, and 3 in circumference, is of a beautiful green color, interlined by red and yellow bands, and by tubercles of the same color, each bearing a long hairy forep.

"A few celebrated naturalists have seen and described this remarkable kind of silkworm. Mons. Deslongchamps has communicated to us a printed dissertation, or memoria, upon all that relates to its classification, its habits, food, and the means of raising it in a domestic way, but at present we will content ourselves to notice its name *Bombyx Papha*, and that of its favorite tree *Ichnu us anguba*.

"I hope, dear sir, that this season will be more healthy and fortunate for your fellow citizens, and for you and your friends, to whom I tender my best wishes and respects. F. PASCALIS."

TRINIDAD.**MINERAL PITCH.**

Captain J. E. Alexander, F. R. G. S. &c. gives the following account of a mineral curiosity in Trinidad, in the Edinburgh New Philosophical Journal.

One of the greatest natural curiosities in this part of the world, is the lake of asphaltum or pitch in Trinidad, situated about thirty-six miles to the southward of Port of Spain. The western shore of the island, for about twenty miles, is quite flat and richly wooded, and though only one or two houses are perceptible from the sea, the interior is well cultivated, and several small rivers, which empty themselves into the Gulf of Paria, afford great facilities for the transport of sugar to the ships which anchor off their embouchures. As Naparima is approached, and the singular mountain (at the foot of which San Fernandez is situated) is plainly distinguished, then the shore assumes a more smiling aspect, here one sees a noble forest, there a sheet of bright green points out a cane-field—cocoa nut and palm trees are sprinkled over the landscape, and gently wave their feathered foliage; now and then a well-built house appears close to the water's edge, with a verdant lawn extending from it to the sea, and the ground sometimes broken into smoothness, and then slightly undulating. The beauty of this part of Trinidad is very great, though, from some undrained swamps, poisonous malaria exhale.

At Poin La Braye are seen masses of pitch, which look like black rocks among the foliage; they also advance into the sea. At the small hamlet of La Braye, a considerable extent of coast is covered with pitch, which runs a long way out to sea, and forms a bank under water. The pitch lake is situated on the side of a hill, eighty feet above the level of the sea, from which it is distant three-quarters of a mile; a gradual ascent leads to it, which is covered with pitch in a hardened state, and trees and vegetation flourish upon it.

The road leading to the lake, runs through the wood, and on emerging from it, the spectator stands on the borders of what at first glance appears to be a lake containing many wooded islets, but which on a second examination, proves to be a sheet of asphaltum, intersected throughout by crevices three or four feet deep, and full of water. The pitch at the sides of the lake is perfectly hard and cold, but as one walks towards the middle with the shoes off, in order to wade through the water, the heat gradually increases, the pitch becomes softer, until at last it is seen boiling up in a liquid state, and the sides of the feet become offensively warm. The air is then strongly impregnated with bitumen and sulphur, and as one moves along, the impression of the feet remains on the surface of the pitch.

During the rainy season, it is impossible to walk over the whole lake, nearly, but in the hot seas in a great part is not to be approached. Although several attempts have been made to ascertain the depth of the pitch, no bottom has ever been found. The lake is about a mile and a half in circumference; and not the least extraordinary circumstance, is that it should contain eight or ten small islands, on which trees are growing close to the boiling pitch.

In standing still for some time on the lake near the centre, the surface gradually sinks till it forms a great bowl, as it were; and when the shoulders are level with the general surface of the lake, it is high time to get out. Some time ago a ship of war landed casks to fill with the pitch, for the purpose of transporting it to England; the casks were rolled on the lake, and the men commenced filling, but a piratical looking craft appearing in the offing, the frigate, and all hands went in chase; on returning to the lake, all the casks had sunk and disappeared.

The flow of the pitch from the lake has been immense, the whole country round, except the bay of Grapo (which is protected by a hill) being covered with it; and it seems singular that no eruption has taken place within the memory of man, although the principles of motion still exist in the centre of the lake. The appearance of the pitch which has hardened, is, as if the whole surface had boiled up into large bubbles, and then suddenly cooled; but where the asphaltum is still liquid, the surface is perfectly smooth.

Many experiments have been made, for the purpose of ascertaining whether the pitch could be applied to any useful purpose. Admiral Cochrane, who was possessed of the enterprising and speculative genius of his family, sent two ship loads of it to England; but after a variety of experiments, it was ascertained that in order to render the asphaltum fit for use, it was necessary to mix such a quantity of oil with it, that the expense of the oil alone would more than exceed the price of pitch in England. A second attempt was made by a company, styled the Pitch Company, who sent out an agent from England; but finding that Admiral Cochrane had failed, and being convinced that any further attempt would be useless, he let the matter drop.

FENCES.

Extract from Gen. Wm. H. Harrison's Address to the Hamilton county Agricultural Society.

In noticing the improvements in rural economy in our own neighborhood, it is painful to observe how little has been done towards substituting more durable fences than those which are in common use. The old worm fence, unsightly and disfiguring as it is to our farms, and withal insufficient and costly, from its great waste of timber, still continues to be the favorite. A change, however, must soon take place, for the country will not much longer supply the materials for constructing it. If any fence composed of rails is used, the best is certainly that of double posts, confined with a cap, and having a worm of one foot to prevent the rails from passing each other. It is much cheaper than the single post fence, more lasting and more easily repaired. If posts or stakes of locust or mulberry can be procured, they will last many years. But the wood of the *Catalpa*, affords perhaps a more lasting material than either, is of very quick growth, and easily cultivated. This valuable tree is indigenous to the lower part of Indiana, and grows to a very large size on the Wabash, and some of its branches. Its ability to resist decay has been sufficiently tested in the neighborhood of Vincennes, both under ground and in contact with it.

Over the little stream of the Desha, five miles from Vincennes, one of these trees had fallen, before any emigration had taken place from any of the states to that place. It was certainly lying there in the year 1785, when a colony of Virginians, from the south branch of the Potomac, emigrated to that place,

and for many years served as a foot-bridge over the stream. I was informed by a gentleman of undoubted veracity, that it was only partially decayed a few weeks since. The same gentleman (Dr. Hiram Dickson) informed me, that a bar post, which was made by his father, and put in the ground at a little stock-ado work, which was erected in the year 1770, and which has been taken up and removed to his own farm, by his brother-in-law, Major Andrew Purcell, is still sound, and answers the purpose for which it was originally intended.

The catalpa is much esteemed as an ornamental tree, but I do not know that it has been used as a timber, any where but in the vicinity of Vincennes. It is now growing very luxuriantly on Mr. Short's and my own farm, raised from the seed."

Prices Current in New York, June 29.

Beeswax, yellow, 18 a 20. Cotton, New Orleans, 12 a 15; Upland, 11 a 13; Alabama, 11 a 14. Cotton Bagging, Hemp, yd. 13 a 21; Flax, 11 a 15. Flax, American, 8 a 9. BAKEWELL SHEEP.

The Subscriber has become agent for John Barney, Esq. for the sale of his celebrated Bakewell Sheep.

The stock now on hand for sale, is the following:

One RAM, three years old, from which Mr. Barney bred last year—a first rate animal. Price \$100.

One RAM, one year old; equal to the other according to age. Price \$75.

Eight or ten EWES, of good age and quality, at prices from \$40 to \$50.

About the first of September next, I shall have from the same flock six or eight Rams of this year's stock. Price \$50 each.

I shall have about the same time, from the flock of another celebrated breeder, a few Ram lambs—half Bakewell and half Southdown. Prices from \$30 to \$40 each. Address, L. I. HITCHCOCK, American Farmer Establishment.

DURHAM SHORTHORN CATTLE.

I have for sale the following fine animals:

One full blood Bull, nineteen months old, by Gloster, out of a first rate full bred cow. He is not above middling size, but is a very beautiful and perfect animal. Price \$250.

One full blood bull, two years old—a very fine animal. Price \$250.

One full bred Heifer, two years old, now springing, but the calf will not be valuable, being (accidentally) by a common bull. She is a very fine Heifer, and will be sold for \$225.

Less than Full Blood.

One Bull, three years old, fifteen-sixteenths Durham; has been pronounced by good judges as fine an animal as was ever in the United States. He would be worth twice the price now asked for him if he had the other sixteenth of Durham blood. He will be sold for \$300.

One Bull, fifteen months old, from good stock, seven-eighths Durham. Price \$225.

One Bull, three years old, half blood Durham, a very handsome animal, and from good stock. Price \$150.

One Cow, eight years old, seven-eighths Durham, a fine breeder, and now in calf by a full blood bull. Price \$100.

Three Milch Cows, half blood Durham, very good milkers, and of good size and form; calves from two to six weeks old. They will be sold for \$50 each.

Address

L. I. HITCHCOCK,
Amer. Far. Establishment.

TWO IMPORTED MALTESE JACKS FOR SALE.

These animals were purchased in Malta in June, 1832, for two officers of the U. S. ship Concord, in which they were imported. The selection was left to one of the best judges in the island, who advertised three months previous to purchasing, for the largest and best bred Jacks, without regard to cost—more than one hundred were offered before a choice was made. They are now about three years old, and stand, one 13½ and the other 13½ hands high, and will yet grow three or four inches; their color is black with fawn nose, eyes and belly. In size, action and vigor, they were believed to be unsurpassed by any Jacks in Malta, and they have been pronounced by good judges, the finest ever brought into the United States. It is deemed unnecessary to say any thing about the superiority of the Malta Jacks; it being well known that they are of the high bred stock of Persia and Arabia.

These animals may be viewed and every information respecting them, may be obtained, by applying to L. I. Hitchcock American Farmer establishment, Baltimore. The price is \$600 each.

HARVEST TOOLS, WHEAT FANS, &c.

SINCLAIR & MOORE, have in store, and are manufacturing a general assortment of HARVEST TOOLS, among which are

100 WHEAT FANS, double and single geared.

300 Grain CRADLES, with Seythes complete. This article is made of the best and most durable materials, and will be warranted as such.

50 doz. Grass and Grain SNEATHS.

30 do. Hay and Manure FORKS.

30 do. RAKES and Wooden tined FORKS.

SCYTHES and Sneaths, hung ready for use.

SICKLES, English and American Seythe Stones, Strickles, &c. &c.

Their Stock of CASTINGS, Agricultural Implements, Garden Tools and SEEDS, is as usual full and complete.

Also, just received from Europe, two bales, containing Lucerne and Ray Grass, Cabbage, Radish, Lettuce, and many other valuable SEEDS of last year's growth. From the appearance of this lot of Seed; and the respectability of the establishment from which they were imported, they can with the greatest confidence recommend them. May 24.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various Sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Berland's Patent Spring Coneave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—An advance of 12½ cents will be noticed in our quotations of Howard street flour; the wagon price is fluctuating from \$5.56 to \$5.62½. Wheat remains about the same as before, while corn has advanced two or three cents, owing to the stinted supply. Indeed there is very little grain coming in.—Rye and oats remain as before.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—1 line yellow, 18.00 a 25.00.—Virginia, 4.00.—Kappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 452 hhds. Md.; 174 hhds. Ohio; 8 hhds. Ken. and 2 hhds. Vir.—total 636 hhds.

Flour—best white wheat family \$6.75 a 7.25; super; Howard-street, 5.75 a 5.81½; city mills, 5.75 a —; city mills extra 5.87½ a —; Corn Meal bbl 3 62½; GRAIN, best red wheat, 1.15 a 1.18; white do 1.25 a 1.31; —Corn, white, 62 a 63, yellow, 64 a 65;—Rye, 65 a 67 —Oats, 36 a 38.—Beans, 75 a 80;—PEAS, 65 a 70 —CLOVERSEED 8.00 a —TIMOTHY, — a —ORCHARD GRASS 3.00 a —Tall Meadow Oat Grass 2.00 a 2.50.—Herd's — a —Lucerne — a 37½ lb.—BARLEY,—Flanders 1.37 a 1.50.—COTTON, Va. 11½ a 13—Lou. 14 a 14½—Alab. 11½ a 13—Tenn. 11a. 12½; N. Car. 12a. 13; Upland 13—14—Wool, Washed, Prime or Saxony Fleece 45 a 50; American Full Blood, 38 a 42; three quarters do. 33 a 38; half do. 30 a 33; quarter do. 28 a 30; common 25 a 28. Unwashed, Prime or Saxony Fleece, 25 a 30; American Full Blood, 22 a 25; three quarters do. 20 a 22; half do. 18 a 20; quarter do 16 a 18; common, 16 a 18 HEMP, Russian, 18 a 190; Country, dew-rotted, 6 a 7c lb. water-rotted 7 a 8c.—Feathers, 37 a 37½;—Plaster Paris, per ton, 4.25 a — ground, 1.50 a — bbl. Iron, gray pig for foundries per ton 33.00 a —; high pig for forges, per ton 28.00 a 30.00; bar Sus. per ton, 75.00 a 85.00.—Prime Beef on the hoof, 5.75 a 6.50.—Oak wood, 3.00 a 3.25; Hickory, 4.00 a 4.50; Pine, 2.00.

CONTENTS OF THIS NUMBER.

Editorial; Value of Cocoons, their Quality and Preparation for Market; Independence—Foreign Markets—Letter from John H. Craven on his System of Farming, as the result of his Experience for forty years, with some Observations on Deep Ploughing, Hillside Ploughs, &c.—Culture of Ruta Baga—On the Smut in Wheat and the Cause of it; Remedy against Smut—Lecture on Horticulture, delivered before the Buffalo Lyceum, in March, 1832, by Lewis F. Allen—Cotton Seed Oil—Elkets of the Winter in Cayuga County, New York—Large Apple Tree—To Destroy the Turnip Fly and other Insects in Hot Beds—Extract from Dr. L. Deslongchamps' Memoir on the Wild Silkworm—Account of a Mineral Fitch in Trinidad—Fences—Prices Current of Country Produce in the New York and Baltimore Markets—Advertisements.

The American Farmer,

Edited by GUNN B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum; due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect AT THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

5. DIRECTION OF LETTERS.—Address all business letters concerning the Farmer, the store, or the agency, to the proprietor, 41. Irvine Hitchcock, Baltimore, Md.

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, JULY 12, 1833.

LARGE RADISHES.—We have now at the Farmer office, three radishes raised by Mrs. Forney, of Reisterstown, that measure as follows:—the first, 18½, the second, 16½, and the third, 15 inches in circumference. Two of them are of the long turnip form, and the other of the long kind. They appear to be hybrids, between the Spanish and common scarlet.

EARLY GREEN CORN.—We have for several years had a variety of early corn of a very extraordinary kind, both as to quality and the season at which it comes into use. We have never failed having it on our table about the first of July, till this year, and this exception was caused by an accidental omission to plant till the 20th of May—and it is even now in full flower, and will be ready for use by the 20th inst. A few persons who have tried it this year, have informed us of the result.—Mr. P. J. Frieze's gardener, sold some of it in our market, on Friday, 21st of June, and Mr. Frieze had it on his table, the 23d of June. Mr. Wm. H. Foot, of Alexandria, writes to us under date of June 25, that he had been eating this corn for more than eight days; and that he has no doubt of having it next year, in the first week of June. He says it is small, yet it is sweet and good. The ears of this corn are about eight to ten inches long, and one and a half, to two inches in diameter. The grain is pure white, and of a good size and depth, and of the most delicate flavor—it is in all respects incomparably better than the small yellow corn, heretofore the first in season; and three to four weeks earlier.—Notwithstanding the great superiority of this corn, we have heretofore been unable to induce our gardeners to adopt it, except in a very few instances.—It will work its way, however, for gardeners will hardly stand by and see one of their profession monopolizing the market, and selling green corn at 37½ cents a dozen, for three or four weeks, as has been the case with Mr. Frieze's gardener this year, without making an effort.

This corn is the result of an attempt at improvement made by the Editor of the American Farmer. He obtained the earliest white corn to be found, and by planting early, and each year selecting the first formed ears for seed, has brought it to the state above described. It grows only four to five feet high, to the top of the tassel; has generally two to four ears on the stalk; bears planting three feet apart, and three stalks in the hill.

HORTICULTURAL SOCIETY OF MARYLAND.

July 10, 1833.

The Council in the name of the society offer the following premiums to be awarded for specific objects during the ensuing year.

For best Strawberries, at least two quarts, to be produced on or before 1st Saturday of June.	\$3
Best Raspberries, three quarts, 2d Saturday in June,	2
Best Gooseberries, six sorts, one pint of each,	4
Best Cherries, four sorts, one quart of each,	2
Best Apricots, two sorts, half dozen of each,	3
Best Pears, six sorts, half dozen of each,	5
Best Foreign Grapes, four sorts, two clusters of each,	5
Best Native Grapes, four sorts, two clusters of each,	5
Best Plums, four sorts, one dozen of each,	3
Best Apples, (early,) four sorts, half peck of each, on or before 2d Saturday of July,	3
Best Apples, (late,) six sorts, half peck of each, after the 1st of February,	3
Best Peaches, (early,) 2d Saturday of August, four sorts, one dozen of each,	5

Best Peaches, (late,) after 3d Saturday of September, four sorts, one dozen of each,	\$5
Best Figs, two sorts, one dozen of each,	2
Best Quinces, two sorts, half peck of each,	2
Best Nectarines, two sorts, half dozen of each,	4

Best Cauliflowers, two at least, to be presented, on or before 2d Saturday in April, 5 |

Best Asparagus, (forced,) two bunches, fifty stalks in each, 2d Saturday in March, 5 |

Best Mushrooms half peck, to be produced before the end of April, 5 |

Best early Cabbage, (York kind,) six heads, 2 |

Best Sea Kale, two bunches, twelve in each, 5 |

Best Rhubarb, for tarts, two bunches, twelve in each, 5 |

Best Beets, at least one dozen, before 1st of June, 3 |

Best Carrots, two bunches, twelve in each, 2d Saturday in June, 2 |

Best Lettuce, (forced,) four heads, 1st Saturday in March, 3 |

Best Lettuce in open ground, six heads, 2 |

Best Onions, from seed in one season, one peck, 3 |

Best Cape Broccoli, four heads, 3 |

Best Egg Plants, at least two, 2 |

Best and largest Tomatoes, one dozen, 3 |

Best Cucumbers for pickling, one hundred, 3 |

Best early Celery, two bunches, 2d Saturday, in October, 2 |

Best Asparagus in open ground, two bunches, 2 |

Best winter Canteloup Melon, two best, 3 |

Offered by an Individual.

For the best Potatoes, one bushel, a silver cup,	\$10
For the best Sweet Potatoes, one bushel, do.	10

Each must be accompanied with a statement showing the kind of seed used, and how cut; the quality of the soil, whether manured or not, the kind of manure, and how applied; the season, whether favorable or otherwise, in a word, the entire process of culture and mode of treatment, otherwise no award.

The committees on fruit and vegetables are prepared to receive for examination any thing that may be sent if deposited at the Farmer office, No. 16 S. Calvert street, on Saturdays, between the hours of eight and nine in the morning. They will report accordingly, and a record will be kept of every thing presented.

ORNAMENTAL DEPARTMENT.

Best collection of Camellias in flower,	10
Best do. Roses, do.	5
Best do. Pelargoniums, do.	5
Best do. Hyacinths, do.	3
Best do. Tulips, do.	3
Best do. Carnations, do.	3
Best do. Dahlias, do.	3
Best do. Chrysanthemums do.	3
Best do. Primula polyanthus, do.	2
For the finest and rarest Exotic Plant,	5
For the best conducted Green-house.	20

By Individuals.

For the best and rarest Tropical Epiphyte, or Air-plant, (orchideous) in flower when exhibited, with account of native country, habit and mode of treatment,	\$10
Best collection of Ericas or Heaths in flower, at least six kinds, (E. Mediterranea and rubra excluded,) with account of culture and treatment,	10
Best dozen sorts of Auriculas in bloom,	3

Competition for these premiums, free to all citizens of Maryland, and of that portion of the District, north of Potomac.

Published by order of the Council,

H. F. DICKEHUT, Sec'y.

To whom apply for further information.
 Editors throughout the state are requested to insert the above.

SHEARING.—Monday and Tuesday last were the days appointed by the proper authorities for performing the annual operation of sheep shearing. At an early hour, accordingly the ceremonies commenced. The number of candidates for the shears were probably seven or eight thousand; and this number would have been far greater, had the flocks been spared by the tremendously destructive storm in March last. On the previous Friday and Saturday, the sheep had been collected from every quarter of the island, driven into the great fold at Miacomet, (the site of an ancient Indian settlement about a mile from town,) selected by their respective owners, placed in separate pens, and subjected to the process of washing in the large pond contiguous. After this preparatory ablution, they were then ready to "throw off this muddy vesture of decay" by the aid of some hundreds of shearers, who began to ply their vocation on Monday morning, seated in rude booths, or beneath umbrageous awnings ranged around the circular labyrinth of enclosures, wherein the panting animals awaited the divestment of their uncomfortable jackets.

The whole ground, occupied by what is termed the "great shear pen," embraces about one square mile.—This space, partially covered with the unshorn and their contented lambs, and in other spots exhibiting multitudes stripped of their fleece, and clamorously seeking their wandering young, presented to the eye and ear of the stranger, sights and sounds somewhat rare. There is something picturesque and unique in the arrangement of the accommodations for those who are engaged in the principal business of the day. Besides these sheds or awnings, there are commonly pitched as on this occasion, some half dozen large tents outside of the great enclosure, furnished with divers holiday refreshments for those who are not particularly particular touching the quality of their viands or of their company. Within and around these tents is carried on all the actual revelry that attends this otherwise quiet carnival: for among the working shearers, industry and sobriety are the order of the day.

We have heard, however, of no disorderly acts, even among the most merrily disposed of the visitors. Both days were remarkably fine; and the whole scene seemed to be highly enjoyed by the numerous strangers who honored our island with their presence—among whom we were very happy to recognize the Rev. President Kirkland, formerly of Harvard University.—*Nantucket Inquirer.*

FOREIGN MARKETS.

LIVERPOOL COTTON MARKET.

Friday Evening, May 31.—On Friday last we raised our quotations ½d per lb. on nearly all descriptions; and we now find it necessary to raise them still further; namely, 2d on American and ½d on other sorts, making an advance altogether during the last fortnight of 3-8d on American, and ½d on other kinds. At these rates spinners, and dealers have taken during the week about 21,000 bags, speculators 7,000, exporters 2,100, making the aggregate sales 30,100 bags. In addition to the above, there was, on Friday night last, a disastrous fire, which consumed 2500 bales of American, nearly 400 of them being fine Orleans, of choice gin marks, which can ill be spared in the present state of our stock of that kind.

At the close of the week, and to-day, there has been a sufficiency of middling quality offered for sale; good remaining comparatively scarce as heretofore.

LONDON, May 28.

Rice.—In rice there is little alteration; mid. white Bengal has been sold in parcels at 11s to 12s. This day by public sale 1,506 bags ordinary Bengal, mid. and broken 11s 6d to 12s, all sold; no alteration in price.

Cotton.—The cotton market continues very firm in price but the purchases are not extensive. The public sale on Friday, 878 bags Madras, sold freely at steady market prices.

AGRICULTURE.

(From the Virginia Farmer.)

PRIZE ESSAY.

ON AGRICULTURE IN VIRGINIA.

BY C. W. GOOCH, OF HENRICO COUNTY.

It has fallen to the lot of the present race of mankind, to live in an age of improvement unparalleled in the history of the world. The arts and sciences have been cultivated to a degree of perfection, and are developing results that had never entered into the imagination of the most sanguine enthusiast of any other period. The intellect and industry of man have made all nature subservient to his purposes. Steam has almost annihilated space; machinery has overcome most of the obstructions of nature, and promises to multiply, to an indefinite extent, articles of comfort and necessity. Revolutions in the moral and political, as well as physical condition of our species, strike the attention in whatever direction we turn our eyes.

But is it not remarkable, that, at such an era, we look in vain for corresponding improvements in AGRICULTURE—that first and noblest of human pursuits? In some of the old countries of Europe surprising advances have been made; and, in several of the northern and eastern states of our confederation, the people have become sensible of the importance of the subject, and are in “the full tide of successful experiment” of an improved system of culture. If, in Virginia, we may congratulate ourselves that several counties, neighborhoods and detached individuals are following these examples, it is questionable whether they are not counterbalanced by the retrograding and desolate appearances that are so often met with in other parts of the state. Take the state altogether, it does not appear to me to improve at all; certainly, not *pari passu* with its population, morals or intelligence. For my own part, I cannot see how it should, under such an accumulation of retarding causes.

The limits of such an essay as this do not admit of a full discussion of these causes. Some of them will, however, be briefly adverted to; since a knowledge of them may be necessary to the proper application of remedies.

Ours is a new country, originally of great fertility. To account for its exhaustion, it will be necessary to look back to its settlement, leaving the intelligent reader to recollect many things which I must omit.

The country below the head of tide water, which now exhibits so many forests of young pines, and so many deserted fields of broom sedge and briars, was the first settled part of the state, and bears more of the destroying marks of man than any other portion. It has also given subsistence to more persons; and has been the hive whence proceeded the great majority of the settlers in the middle and western parts of the state. It gave birth to, and raised more than double its proportion of that swarm of Virginians who have peopled an empire in the west and southwest; and it still furnishes more than its ratio of the emigrants who cross the mountains. Its soil was exceedingly fertile when first stripped of the primeval forests. The aborigines exterminated the first settlers, and nobly warred against their successors. After the settlements were considered secure, and emigration from the mother country had increased nearly to inconvenient numbers, the exasperated Indians kept them within narrow limits, and compelled them to cultivate their lands without rotation of crops or any ameliorating system. The settlements, nevertheless, progressed with the increase and wants of the population, driving the Indians before them. In this way, parts of lower Virginia were nearly exhausted before the settlements reached the mountains. But the tract of country above the head of tide water scarcely felt this Indian pressure; for, when the Indians were

driven into the hills, and found the tide of white men rolling upon their retreating steps, they took refuge at once beyond the Blue Mountains. The advancing settlers then spread out, and located themselves wherever they pleased. The laws permitted them to acquire ownership over land at the price of a few shillings per hundred acres. The policy of these laws was to encourage emigration from abroad and people the country as rapidly as possible. In one respect these laws had a pernicious effect on the agriculture of the state. They enabled the aristocracy, then numerous and wealthy, to locate and appropriate to themselves and their heirs, vast tracts of the most fertile lands; which, for several generations, were left uncultured, or were rented out to persons, by whose unsparring cultivation they were the sooner impoverished; and after, as well as before the Revolution, it had a tendency to keep up an inequality among the people. May not too great a reduction in the price of the public lands, now held by the United States, have a similar tendency, and cause a still stronger stream of emigrants to issue from the old states? This is an incidental question which cannot escape the solicitude of a Virginian at this moment. But it belongs to politics, with which this essay has but little connection.

Of all the causes which have produced the present dilapidated appearance of Virginia, and prevented agricultural improvements, the most operative have been the cultivation of tobacco and the existence of slavery; I mean negro slavery, in contradistinction to white slavery! Whilst I shall speak freely of the disadvantages of the *one sort of slavery*, as coming within the proper sphere of my remarks, I cannot feel authorised to go out of my way to comment on the other. All that I ask is, that improper inferences may not be drawn.

It is probable that seven-tenths of the land that has been cleared east of the mountains has undergone the scourge of the tobacco crop. Tobacco has been the staple of Virginia from its settlement. Its culture was greatly encouraged by English and colonial legislation, and has not lost its importance on the statute book of later times. Formerly it was a sort of cash medium of remittance to the mother country, and a circulating currency among our citizens. The *inspectors' notes* passed as readily as do the bank notes of the present day; and individuals gave their bonds for tobacco as often as for money. The exhausting effects of its culture arise as well from its heavy draits upon the soil, for the juices which contribute to its size and weight, and its oily, narcotic qualities, as from the necessary process of tillage. The land is stripped of every thing, down to the cover of decaying leaves; the rich vegetable mold that had been accumulating for centuries is then scraped up into hills, mixed with a portion of the soil from below. For many years past, previous coulturing has been found necessary, in consequence of the injury done, and compactness given to the soil, by the long tramping of domestic animals. This mold, thus suddenly exposed to the atmosphere, the rain and the sun, is soon evaporated, or washed into the valleys. Being soluble in a great degree, its evaporation is, in my opinion, as great as its consumption in every other way; for it rarely washes off under the tobacco crop, except from steep hillsides. The elevation of the tobacco hills cause them, before shaded by heavy plants, to dry quickly, both by sun and wind. To this we may add the frequent stirring of the ground when the plant is young, by the process of weeding and hilling up.

Here, by way of digression, I must be excused for a few remarks, which would seem to have a more appropriate place elsewhere. But as they apply to this mold,—this young and tenderest part of all soils,—I insert them in this place.

The vegetable mold found on the top of all virgin land, varies in thickness, according to circumstances. But these circumstances involve a philosophical in-

quiry, into which the limits of a fugitive essay do not permit me to enter. Why is it that the leaves of the forest so rapidly decay in the rich woodlands of the western country, and that they are covered with grass? Is not this the case sometimes in the forests of Virginia? Why do the leaves of the walnut, and some other trees, decompose so rapidly in all situations? and why is the ground about them richer than that adjacent? The mold on the top of new land ought never to be broken up and exposed, if it can be avoided. On the contrary, it ought to be turned under and mixed with the under soil. This process will be a little difficult in new ground; but the benefits resulting from the mixture and fermentation will more than compensate for the trouble. I would recommend that such land be prepared as well as possible, and planted in corn, without destroying the cover of leaves by the barbarous and common practice of raking and burning. Corn is a vigorous plant, and with the aid of hoe work, will be greatly benefited by the half-decayed twigs, leaves and wood, which cover our virgin land. Neither wheat nor tobacco will grow so well amidst the trash of a new ground. The working will intermix the whole mass of litter with the mold and a small part of the next stratum. And thus when the corn crop comes off, the previous stirring and amalgamation of the mold, leaves, twigs, rotten wood, and a part of the sub-soil, will be a preparation for after crops. It is true, that the greater the quantity of litter the less corn will the land yield. If we could spread lime or marl, or even the more common article of plaster, upon it, before coulturing and working, the corn crop would be relieved from its pale green, sickly appearance, and give more grain, and that ripe. The frosts of the next winter will prepare this land for a crop of tobacco or small grain. If the soil be good and the owner wishes to make tobacco, he will get more the next year, and even the year following, than he could have made the first year, after the old plan of *raking and burning*. We have sought, as our ancestors did, every mode of destroying the vegetable mold upon our lands, and of the materials out of which it is produced. My idea is, that with a farmer, or even the tobacco maker, who has lots or flats, it would be best to put his new land, managed as I have described, in small grain the second year, followed up by clover and plaster the third and fourth years. After this it will have yielded him a fair return, be richer than when cleared, and be capable of producing a good crop of any thing he may wish to cultivate. And it may be progressively improved by a proper rotation, if there be a clay foundation; if not, it can be kept *productive* and comparatively rich. The chief difficulty in reclaiming exhausted land arises from the absence of putrescent vegetable matter, which it originally contained, and which has been destroyed by severe cropping, bad tillage and close grazing. It is in vain that nature annually attempts to renew this essential food of plants, when the rapacity of man and beast unite to defeat her efforts. But to proceed.

Tobacco leaves but little offal or manure; and it comes off the ground so late in the fall, that no sheltering or improving after crop follows it. No crop remains so long on the hands of the cultivator, or requires such constant and fatiguing labor. It is generally from twelve to eighteen months from the sowing of the seed to its arrival at market. All this time it requires constant attention, if not the constant application of labor. The planter formerly relied upon it as his only source of income; for he seldom made corn for sale, and often less than he wanted; and the wheat crop went to make up deficiencies, pay taxes, &c. In this respect there has been a favorable change within the recollection of the writer. Woodlands adapted to tobacco have now become scarce; and it is chiefly raised on manured lots and rich flats. Necessity has thus driven the planters to the new practice of taking care of manure; but they devote nearly all of it to their tobacco lots. More attention

is now paid to grain crops than formerly. The three shift system is the one commonly pursued, by which each field is improperly said to rest one year in three; but under the kind attention and constant presence of all the four-footed animals on the farm. It, however, gets a little respite after harvest, when the stock are turned into the grain fields to glean them, and destroy the young after-growth of weeds and grass, which provident nature throws up as a protection from the sun, and as a fresh supply of vegetable matter to sustain the growth of the next year. In the rotation of crops, she sets us a beautiful example. Look to the various productions she sends forth on new land, and especially when we destroy each production. The next is always different from the immediately preceding one. This land-destroying, Virginia system of husbandry, has been practised by almost the whole community until within a few years, and a majority of our people still pursue it. And is it to be wondered at, that after the destruction of so much of the soil by tobacco, and such long perseverance in this system, our lands wear out, and yield such scanty returns for the labor of the husbandman?

If you examine the plantation of the tobacco maker, you find every appearance of poverty or unpardonable neglect. The owner will acknowledge that things ought to be and might be better; but that he has no time to spare, owing to the pressure of his crops, particularly his tobacco crop, which interferes with all his other operations throughout the whole year. There is much truth in his excuses; for in January, February and March, he is clearing new grounds; preparing and burning plant beds; fencing; manuring, and fallowing tobacco lots; sowing oats, ploughing, and preparing corn land; and, either stripping or picking tobacco; perhaps both. In April, May and June, his toils begin to assume more interest, and require more exertion; his whole crop of corn is to plant, replant, thin, weed and cultivate; the tobacco hills are to be made, turned, cut off, and the first plantings made. The old crop of tobacco is yet to be finished prizing, and hauled to market, if not previously done; experience having proven that the longer it is kept before prizing, the sooner and better cured it will be—especially for shipping. Harvest is now at hand; but that period of industry and festivity to the mere farmer, brings with it sleepless toil and accumulated cares to the planter. The replanting tobacco, the topping of that which stood well, and the most careful tillage of the whole with the hand hoe, press him on the one hand; whilst, on the other, his late corn is not yet laid by, and his grain requires cutting. From the pressure of the corn and tobacco, the grain is too often literally mowed down and shocked about the field in a still more hurried and slovenly manner, to be half destroyed by winds and rains. Throughout the months of July, August and September, not a moment's respite is enjoyed. The tobacco crop has to be gone over more than a dozen times in the laborious operations of topping, succoring, worming, working, cutting, piling, removing to the houses and curing. The small grain must be hauled up and stacked, and when the depredations of the weevil leave no other alternative, the wheat is gotten out and carried to market. The fodder soon has to be secured, and this comes on just with the cutting of tobacco. During the other three months of the year, the better securing of the fodder, the gathering and housing of the corn, and the sowing of the next year's crop of winter grain, leave no leisure time to the poor planter. The tobacco, although housed, must be closely watched; the latter cuttings cured; and then commence the tedious operations of striking, stripping, assorting and bulking away. Besides these conflicting objects of attention, there are many others that demand the care and attention of the planter.—The whole circle of the year is one scene of bustle and toil, in which tobacco claims a constant and chief share. No time can be devoted to the planting of fruit and ornamental trees—to ditching—cleaning

up waste and reclaiming galled spots—making and spreading manure on the grain fields—deep and careful ploughing—sowing clover and plaster—or providing comfortable shelters for stock in the winter. The dwelling house, yard and garden enclosures and all the out buildings too often fall into decay for the want of some trifling repairs, which the crop hands might make, if they had time. The plantation soon looks tattered and almost desolate—galled and gullied hill sides and sedgy, briary fields show themselves in every direction. The profits from the destruction of one plantation, are applied to the purchase of another and of more negroes. The new one is put in charge of an overseer on shares, who soon brings it to greater sterility and desolation. It is in this way that most of the best lands in Virginia have been brought to their present condition, and have been, then, deserted by the destroyers.

But the existence of negro slavery among us, has, in a great degree, influenced the mode of destroying our lands, and hastened its accomplishment. In former times the exactions of the master were only limited by his cupidity. In this respect, a favorable change has taken place. Our slaves are now as well fed and clothed and enjoy as many comforts as the laboring class in other countries; and they have improved proportionably in their appearance and intelligence. It is not my purpose to touch the dark question which involves their future destiny. Its agitation has, already, on two occasions, roused a state of feeling which verged to desperate extremes. Whatever evils may attend it, the *right of property* can never be permitted to be questioned by others.

The possession of slaves has had too great a tendency to make the owner and his family unwilling to take upon themselves any part of the drudgery of out-door business; and too many of our people think it disreputable to labor. We have been accustomed to be waited upon from our infancy, and consequently, keep about us too many wasteful and almost idle domestics. Exempted from labor and even from the common cares of business by the employment of agents, we imbibe habits and modes of thinking unfavorable to physical improvement or successful agriculture. The unfinished houses and projects half executed, which are to be seen throughout the state, are evidences of the meaning and truth of this remark. That the ease in which we have so long indulged, favors the attainment of literary and political knowledge and personal accomplishments is manifest from the acknowledged proficiency of Virginians in *these respects*. But, whilst we are all politicians, to a man, it is to be regretted that our achievements in the arts and sciences bear no just proportion to the opportunities we have had. May not this arise from the ill judged devotion of too much time to pleasure and dissipation? It is unfashionable for a genteel or educated Virginian to apply himself to the details and cares of the humble, but useful vocations of life. And, hence, it is, that most of the sprightliness and genius of the state have been applied to one of the two learned professions. The pulpit is of late, putting in its claim to the aspirations of our youth.—Has not agriculture and the arts been too long robbed in this way, of their just share of talents—of men whose intellectual endowments might have given a more winning countenance to the venerated mother of us all? Of the legions of young men who annually embark in the professions, how many are there who rise to eminence? How many, that, from disappointment and chagrin, betake themselves to dissipation? How many linger out a brief life of listlessness and *expectation*: almost a burden to themselves and an expense to their parents and relations? How many, with consciousness of merit and a determination not to become drones, reluctantly emigrate from the scenes of their boyhood and the bones of their ancestors? May not I ask what portion of all these, if brought up to the habits and cares of business—to the quiet and healthful pursuits of rural life—or to the cultiva-

tion of the useful arts, would have been lost to the state, either by self destroying habits or emigration? The effects of slavery upon our daughters, though not less striking and pernicious, are less seriously felt by *agriculture*; but it does not seem to accord with the object of this paper, to dwell upon them.—If these effects be seen in the lofty pride of our women; in their admiration of *genius*, intellect and valor, and a *repugnance to domestic duties*; they are also to be seen in their virtues, and, especially, in their chastity. The profligate cannot fail to see and feel the meaning of this remark.

The white man who has to labor for his support, does it with an unwilling spirit. He sees the exemption enjoyed by others; and, if he does not fancy himself equally entitled to it, is too apt to repine at his lot, or migrate to some new state, where he will be upon a footing of greater equality with his neighbors.

But, independent of the enervating and paralyzing effects of slavery upon all of our *white population*, there are pecuniary losses, arising from it, that are heavy drawbacks to the agriculturists. Most of the labors of agriculture have been confided to careless overseers, and still more careless operators. The slave feels no inducement to execute his work with effect.—He has a peculiar art of slighting it, and seeming to be busy, when, in fact, he is doing little or nothing. Nor can he be made to take proper care of stock, tools, or any thing else. He will rarely take care of his clothes, or his own health, much less of his companions when sick and requiring his aid and kindness. There is, perhaps, not in nature a more heedless, thoughtless human being than a Virginia field negro. With no care upon his mind, with warm clothing and plenty of food, under a good master, he is far the happier man of the two. His maxim is, "Come day, go day, God send Sunday." His abhorrence of the poor white man is very great. He may, sometimes, feel a *reflected* respect for him, in consequence of the confidence and esteem of his master and others. But this trait is as remarkable in the white as in the black man. All despise poverty, and seem to worship wealth. To the losses which arise from the *dispositions* of our slavery must be added those which are occasioned by their *habits*. There seems to be almost an entire absence of moral principle among the mass of our colored population. But details upon this subject would be here misplaced. To steal and not be detected is a merit among them, as it was with certain people in ancient times, and is, at this day, with some unenlightened portions of mankind.—And the vice which they hold in the greatest abhorrence is that of telling upon one another. There are many exceptions, it is true; though this description embraces more than the majority. The numerous free negroes and worthless, dissipated whites, who have no visible means of support, and who are rarely seen at work, derive their chief subsistence from the thefts of the slaves.—These thefts amount to a great deal in the course of the year, and operate like leeches on the fair income of agriculture. They vary, however, in every county and neighborhood in the exact proportion as the markets for the plunder varies. In the vicinities of towns and villages, they are the most serious. Besides the actual loss of property occasioned by them, they involve the riding of our horses at night, the corruption of the habits and the injury of the health of the slaves; for whiskey is the price generally received for them. These evils have been always felt; but they have become so great of late, that the legislature ought to provide a more efficient remedy. The statute book would seem to contain one.—"Whether the defect be in the law or in its execution," is not for me to decide. It sometimes happens that the head thief on a farm is in partnership with the overseer; and when this is the case, the husbandman has no chance for profit.

Another great cause of the dilapidated appearance

of Virginia is the semi annual wave of emigration which has so long rolled from her bosom in a western and south-western direction. It has not only swept off the most enterprising portion of our people, but also much of the capital and moveable property of the state. Nor is this all: the price of land has been kept down by the great quantities of it brought into market by the emigrants. Instead of improving those we held before, we have been tempted to add to our possessions exhausted farms and plantations. It has been the custom to go in debt for two-thirds of such purchases. The emigrants, besides taking with them every thing they can, draw annually, for three years, upon the earnings of their old neighbors. Thus the landholders have not been able to accumulate a *disposable* cash fund, to be applied to improvements and the purchase of better implements, &c. On the contrary, they are too often forced to cultivate their lands with greater severity, to meet these payments.

The great fertility and cheapness of western lands, and the increased value given of late to every thing in the west, by the use of steam on its noble rivers, have been inducements to emigration too strong to be resisted by a people who find it laborious to earn a mere subsistence in the land of their fathers. I need not advert to the wonderful, the magic growth of the "mighty west"—that fairy land of imagined manna, and of milk and honey. During the ten years, from 1820 to 1830, the increase of population, and rate of increase, will be seen from the following table:

States.	Increase in ten years.	Rate of increase per cent. in ten years.	Present population.
Alabama	181,096	141.6	308,997
Mississippi	61,358	80.1	136,806
Tennessee	264,009	62.7	684,822
Kentucky	124,527	22.1	688,814
Ohio	356,203	61.2	937,679
Indiana	194,401	132.1	341,582
Illinois	102,364	185.4	157,575
Missouri	73,488	110.4	140,074
	1,357,449	Aver. 99.4	3,396,379

These rich and flourishing states have grown up within a short time. It is not pretended that all the emigrants by whom they have been peopled went from Virginia. But it must be conceded that this state furnished a very large proportion of them; to say nothing of the number of her sons who migrated to the Carolinas, Georgia, Florida, Louisiana, Texas, Arkansas and Michigan. The fact that so many of our friends and relations have left us and are prosperous and happy in the new states, has a tendency to make us restless and dissatisfied, and will continue to keep up, and perhaps increase the spirit of emigration.

I have given a rapid sketch of some of the great causes of the depressed condition of Virginia, and particularly of her agriculture. But there are many others,—some growing out of these, and others independent of them,—which I must leave to suggest themselves to the mind of the intelligent reader.

Now, what is to be done to arrest these evils—to give new hope and confidence to the desponding minds of our citizens, and retrieve the falling fortunes of the good old *mother state*? This question addresses itself to the heart of every individual patriot: it solemnly appeals to the hearts and the heads of our legislators, and all others in authority among us. The thing is practicable; and only requires a small sacrifice of pride, individual interest and local feeling. Let us abandon and discountenance that aristocratic feeling which we have inherited from our ancestors and have too long cherished. Let us attend more in person to our business, no matter what that may be, instead of trusting to agents or deputies—retrench expenditures, particularly of living—bring up fewer of our sons to the learned professions, and more of them to industry in agriculture and the useful trades and arts. In this way we may dispense with many

careless and costly overseers, with the number of artists, engineers, skillful mechanics, and even with the hosts of northern schoolmasters, who find annual employment alongside of our idle sons. Let us abandon the besetting sin of procrastination and making good resolutions that are never executed—adopt an improved system of cultivation—make all the manure we can, and reclaim a given number of acres of land every year, according to our means, if it be but one or two—use better implements of husbandry—prepare for it, and take better care of our crops and stock—reduce the latter to a number that can be well fed and kept in high order, and one-fourth will give more profit than the whole; and as much manure, without extensive and ruinous grazing of the fields. Ought we not, as soon as possible, get the best breeds of stock, and gradually adopt the *soiling* system; or, in other words, the plan of keeping our stock within limited bounds, and *feeding* them abundantly with food, cultivated and prepared for them, throughout the various seasons of the year? One milk cow properly housed and fed throughout the winter, will give to a family more milk than half a dozen in our common way. But experiments and their results upon this, and almost all the branches of rural economy, have been made known to the public, and may be referred to. The nature of this article prevents my going into specific details; since almost every subject would be the ample groundwork of a little volume.

But why should we not get up agricultural societies in different parts of the state, and *keep them up* by zealously encountering some little trouble and expense for that purpose? It is an old saying, that "what is every body's business is nobody's." This aphorism is *not true in politics*; and why is it that we cannot feel a kindred zeal in what is the foundation and life-spring of all other human vocations? In politics every man takes an interest: we are ready to attend public meetings—to discuss the topics of the day around our firesides—at cross roads, and all the sorts of shops and meeting places in every county. We cheerfully pay our money to support profligate and hired editors, who either gratify our taste for slander or minister to our bitter prejudices; and yet we are unwilling to pay a small sum for the support of an agricultural journal or an agricultural society! Our civil and political rights are very important; but there are "matters and things" which address themselves to our next dearest sublimity interests, and which we ought to attend to, because they involve so large a portion of our comfort, prosperity and happiness. The human race is struggling to get onward in almost every thing else but in the homely pursuit on which all others depend—*agriculture*. Yes, every thing depends upon it at last; for it supplies the substantial comforts of life. What a host of men have we in this half peopled world of *ours*, where there is so much land and such ample elbow-room, who literally live upon the industry of the husbandman? It is true that many of them are necessary auxiliaries. But how many of the various *craftsmen*, including the *buttern* and *shuttle*, and other *players*—whether in the forum, the sick room, the pulpit, the necessary departments of public service—in the various and ramified employments of commerce, or in the circles of benevolent societies, and other trades devoted to our *instruction* and *edification*—how many, I ask, among all these, are willing to walk upon *old mother earth*, during half the year, without double and treble *foot clothing*? Many of them afford us necessary comforts and conveniences, and even the pretty things upon which we may serve up in style the productions of the husbandman; and others live by their talent for offering up to Heaven fervent thanks for the privilege extended to all of *consuming* these savory viands. But, after all, do not the varied and indispensable vocations of human intellect and human industry mainly depend upon the *agricultural* community?—upon that portion of our population the

least respected and the least regarded by the law-makers and the patrons of other and less valuable pursuits?

Is not husbandry the great preponderating interest in America? Look at the happy varieties of our soil, climate and productions—look at the vast territory of unimproved and uncultivated land, inviting the hand of industry, and promising the *slow*, but *certain* rewards of peace, health, abundance. And, with all these things staring us in the face, is it not preposterous in the federal government to wish to hurry things beyond their natural gait—to turn us into a nation of *spinners* and *wavers*, and *handy-craftsmen*? The talents of the state have been too much devoted to something other than our *primary* interest; and that is the reason, as I have before suggested, that Virginia has sunk to what she is. Is not the time for her renovation at hand? Many of us have been unwilling to *run away*, either from the increasing gloom and dilapidation which annually thicken around us, or from the moral depreciation, including our own faults, in which we find ourselves annually involved. I say that *many* have been influenced by this consideration. We have expected a sense of returning justice on the part of the federal and state governments. We have looked to better times, and suffered present evils, under the confident expectation that justice would be done to us by the federal government, in relation to the tariff, &c.; and that our own drones in the state legislature would be either removed or awakened to a sense of their obligations to do something for the farmers and planters, instead of spending their time in abstractions about federal politics or catering for the interests of deputy sheriffs and clerks of courts. This remarks, so far as federal politics are concerned at *this time*, may not be strictly just; for I acknowledge that South Carolina has placed the union in jeopardy. But my essay has nothing to do with that.

If the farmers and planters of the United States choose to be made the pack horses on which all other interests may ride up the hill of prosperity—be it so, in the name of God! We have broad shoulders—brawny hands; and very little ambition, but to surpass the band-box, and handy-craft, and tongue-craft gentry in all the substantial of honest dealing and warm hearted, though blunt, hospitality. I am exclusively a farmer; yet, I have seen something beyond the scope of rural cares and country rusticity. And may I not ask, after all, who, in the whole circle of human employments, enjoys more substantial happiness, and feels a loftier independence than the virtuous warm-hearted *husbandman*? All that surrounds him is his, and depends upon him. Every thing that he consumes is the product of his own industry, except a few luxuries, which he readily procures in exchange for his surplus articles or for the price of them. His necessary exercise in the pure air invigorates both body and mind. Who eats his meals with more zest, or sleeps sounder? Who is less annoyed with ennui—with *dyspepsia*—with other *fashionable* diseases? Who enjoys the company of a friend or neighbor with more heart-felt pleasure—or is more willing to offer the hospitalities of his roof to the stranger?

But why should not the husbandman, with these pre-eminent claims, receive some share of justice from the government? Some little crumb of comfort—and if not even a *crumb*, why should he not be *exempted* from the maintenance of speculation, cupidity and avarice? We have no hope but in ourselves. Let us then determine upon a change. We cannot be worsted much. Why should we not instruct our bourgeois to make more ample provision for educating the people, and for carrying on a system of internal improvement commensurate with the wants and the rich resources of the state?—These subjects are intimately connected with the prosperity of agriculture. I will not insult the public understanding by supposing that any thing is necessary to be said in behalf of education. The only difficulty is, that the men of proper

ty are too unwilling to pay a small tax to enlighten the minds of the children of their poorer neighbors. They seem to have forgotten that the law of entails is abolished; and that in the revolutions of fortune their own children and grand-children may stand in need of a similar mite from the very persons whom they seem now so unwilling to aid. They also seem not to perceive that by some trifling contribution they may dispel some of the clouds of ignorance by which they are surrounded, and improve the morals and habits of their neighbors.

A judicious system of *internal improvement*, projected upon a liberal scale, and prosecuted with adequate means and becoming energy, cannot fail to put a new face upon the affairs of the whole state. In its prosecution it must increase the value of labor and give employment to the restless part of our population; giving, at the same time, fresh expectations and hopes to all desponding minds. If it does not at once arrest the destroying tide of emigration, it cannot fail to do it in a few years. Need I dwell upon the rich and varied resources of this great state?—resources which would be soon developed, if the means of transportation and intercommunication were only afforded? In consequence of the great expense of transportation to market, the productions of the interior are confined to such articles as will bear the expense. But if we had the necessary roads and canals, an immediate change would take place in the pursuits of the planters and farmers.—Their industry and economy would be stimulated, and cause the production of a variety of articles which would add new wealth to the state, new comforts to the producers, and materially change the blighted aspect of the country. There is nothing to be alarmed at in the expense of a well planned road or canal, although the amount may at first seem to be large; for the income will soon pay it off. In the mean time, the advantages to be derived from the increase in the value of property, the new articles that may be carried to market, and the saving in the expense of carriage, will all more than compensate for the cost of the work. But it is the misfortune of Virginia, that on this, as on many other subjects, her local interests are not homogeneous. We have a low-land, a south-side, a middle, a valley, a northwestern and southwestern interest. Some of these, either in the whole or in part, harmonise on improvements. But has not the time arrived when these jealousies and conflicting pretensions should give way to the common good? It is impossible to undertake at once, all the needed improvements in every section of the state. Ought they not to be executed, if the state is to participate as she ought, according to the scale of their value and importance? If local feeling and contrariety of views in the legislature disqualify that body from arranging the order in which such improvements ought to be made, what objection can there be, to the employment of commissioners and engineers from other states, to fix the scale of importance and order of time for their construction?

It is due to candor to acknowledge that no part of the state has received less public bounty, in the way of improvement, than the country below the head of tide water, whilst they have contributed their full share to the internal improvement fund. But, prospectively, they are deeply interested in the improvement of the whole state. Although they have level roads and navigable waters, there is scarcely a county in lower Virginia, in which some valuable improvement may not be made, fully equal to its share of general contribution. Justice would seem to require that these should not be overlooked. But, to return from this digression.

The defects of our police laws; the complication of our whole code, and, especially, the vexatious and expensive delays of litigation, bear upon all classes of productive industry, for the benefit of the non-producers and inefficient.

It was not my intention, in the commencement of

this paper, to dwell on the several crops cultivated in Virginia; or on the best modes of tilling each.—Such a range of inquiry is beyond my ability; and, if it were not, it would require a ponderous volume to embrace it. We must recollect that our state is divided into three great territorial divisions, in each of which the staples, the soil, and the climate, differ essentially. Below the head of tide water, corn, cotton, oats, peas, potatoes, &c. are the chief objects of culture.—Above the head of tide water and to the North mountain, tobacco and wheat; and, in the valley, may be added hemp, live stock, &c.—Beyond the North mountain, grazing, and fattening stock for market may be considered as the preponderating interest. Systems of tillage and management, quite different in many respects, apply to each portion of the state. The single subject of the management of *manure*, both in regard to the making and application of it, presents an illustration of my idea. In the lower country, we have an abundance of shell-marl, sea, swamp, creek and river mud; pine beads, kelp, and exhaustless quantities of vegetable matter on the swamps and marshes; we only want the industry to collect and use them. The newly discovered quantity and value of our marl resources seem to favor the hope, that from this source alone, a marked change will soon take place in the appearance of this, most tattered, and desolate-looking portion of Virginia. Albemarle is the native county of the writer; yet, he is not blind to the beauties, the advantages and value of lower Virginia.—Its great misfortune has been, the facility with which a subsistence could be procured without much labor. The palatable productions of the air, the land, and the water, have too much enervated, may I not say, paralysed, the energies of the people. At one time, the monopoly of property and the proud aristocratic feeling of the Dons, kept every thing subservient to them; and, to them, and their pride, and anti-republicanism, lower Virginia is more indebted for her drooping appearance, both in the general aspect of the country, and the *general mind*, than to any thing else! The effects of *emigration* would not have been so serious in lower Virginia, but for the pride of "*untitled nobility*."—Thank God, that there is now some hope for a change! The revolutions of fortune have left but few of the *old gentry* who are not, more or less, disposed to mingle without conscious disgrace, among the *common people*: and, always, when they want office or public favor: and those who do remain, of that caste, whilst they may justly feel the pride of *pedigree*, must feel also a conviction, that their ancestors have a little over-stepped the mark, on this subject. But, things are getting right; and, it is unseemly to talk too much about a *departing shade*! We ought to let it pass, because we have more recent, and now, more formidable pretensions to combat.

The other parts of the state are less amply supplied by nature with materials that may be employed in fertilizing the soil. From the operation of this remark, ought to be exempted all that region of country in which *limestone* is found in abundance. This exemption would embrace a large, and perhaps, the most desirable portion of country, beyond the Blue Ridge. In that section of the state the abundance of limestone and calcareous earth or marl, leave those who reside among these advantages, no excuse for not enriching their land. A narrow vein of limestone commences at the Potomac on the east of the Ridge, and runs parallel to the mountain at about an average distance of twenty-five miles from it, quite to the North Carolina line. This vein is, in many places, a considerable depth below the surface. But where it does appear is of good quality and might be usefully employed in fertilizing the adjacent lands. In the line of this vein, the writer has seen immense quantities of blue clay marl, resembling limestone in the water courses, and where the topsoil has been washed off on hill-sides. This substance is of the consistency of Fuller's earth; but effervesces powerfully in

acids. When applied as a manure he has seen the most surprising results. And, yet it is not strange, that neither this substance nor the limestone, is any where used to much extent? The marl of the lower country is becoming an article of commerce. It is most abundant on the navigable rivers and bays, and vessels have been some time employed in transporting it to the cities north of us, where it sells from 10 to 12½ cents per bushel.

We have too long trod in the old and beaten track of our ancestors. Has not the time arrived when the agricultural community ought to rouse from this lethargy—avail themselves of the wonderful improvements of the age—at any rate show a disposition to avail themselves of all new discoveries, and to better their condition? Why should we permit every thing else to get so far the start of us? Our neighbors to the north, and even to the west deride and shame us, by their superior skill and industry, and the consequent superior advantages and comforts they enjoy! Then, let us "be up and doing." We have the climate, the soil, and other superior advantages that a kind Providence has bestowed upon us. We have every thing necessary for the exhibition of enviable scenes of rural beauty, prosperity and happiness—yes, every thing but the *industry*—and a *disposition* to do so. How long will we submit to such a just reproach!!

HORTICULTURE.

(For the American Farmer.)

TRANSPANTING POPPIES AND LUPINS.

In *Thorburn's* "Directions for the Management of Flower Seeds," it is said, that "any thing may be transplanted that we know of, except the *poppy* and the *lupin*, and these we believe to be impossible. They must, therefore, be sown where they are to blow." And the same opinion in regard to lupins was held by the celebrated *Pursh*.

This notion is so different from the results of my experience, that I would inquire what poppies, and what lupins are meant? of the transplantation of annual poppies, I know nothing; but I have been uniformly successful in transplanting both the *oriental poppy* and the *Caucasian poppy*: I have no recollection of having ever lost a plant. I cannot say as much, however, in regard to lupins. I think I have lost one or two out of more than a dozen *Lupinus perennis*, which were brought from the woods into the garden; but considering the great change in their situation, I conclude that they bear removal as well as the average of wild plants. This spring I have also transplanted several other species of lupin with the most perfect success, after the plants had three or four leaves besides the cotyledons. These were *Lupinus nootkatensis*, *L. macranthus*, and *L. luteus*. The last was a remarkable case, and will show how well this plant can bear the operation. It was out in four leaves, when I observed it in a withering state; and suspecting some mischief at the root, I took it up, and cut off the diseased part, removing the lupin into another border. It was shaded by a flower pot with a hole in the bottom; but the plant continuing to decline, I turned off the pot, relinquishing all hopes of its recovery. After a few days, however, to my surprise, I found it putting forth new leaves, and it is at this time in a flourishing condition. A GARDENER.

WILLIS' GREAT GRAPEVINE.

MR. SMITH: Port of Oxford, June 16, 1833.

Dear Sir,—As to my great grapevine, as it is called, I must inform you that the first of the sort came from the island of Jersey, between England and France; but many people have contended and called it an American sort. I cultivated the sort many years with success, before I planted this in my yard, and when I put this there, I applied my new discovery of

the soap suds. &c. &c. twice a week on its roots, and the first year's growth and a little more was eat to the earth by a cow that got in one night; I then trained the first sprout that it put forth to forty-five degrees elevation, with crooks in the stem. At three or four years' growth, I was taking down some valuable fruit trees; I then pruned off about two-thirds of the vine, and trained the other to cover the yard before the door for a shade; and I still order the suds to be applied at least twice a week. Its growth took the attention of so many strangers that some thought there was more than one stem to it, and it was examined by some, thinking it was several vines put together. My respectable friend, Mr. Hammond, the President of the Easton Bank, came and viewed it, he had lived in Jersey, and said it was much like the sort in Jersey, that run over the houses, and the fruit gathered out of the windows, but when he tasted it he said it was not the same taste; but if it was ripe it would be as good, and much like it. I find it is best to hang on late, even until winter, and it is a fine table fruit. It is now in its eighth year's growth, and is more than one hundred and twenty yards, if opened out a little, in circumference; the stem only twelve and a half inches round. What would it be if taken care of, and allowed to run until old, as the Hampton Court palace vine, in England, planted in the reign of King William? A vine to grow fast and live long should be taken far from the root of the mother vine, or raised from seed. I am, dear sir, yours, with due respect,

JOHN WILLIS.

(From the Southern Agriculturist.)

OBSERVATIONS ON THE PLANTING OF THE VINE AND ROT IN GRAPES.

Columbia, S. C. May 28, 1833.

Dear Sir.—I have observed in the number of the *Southern Agriculturist* for the month of March last, a communication from that very interesting and persevering cultivator, Mr. Abraham Geiger, on the subject of the culture of the vine, and particularly on the manner of planting it to the best advantage and least expense; and also on the cause of the rot in grapes, &c. Any thing proceeding from so intelligent a source is highly deserving of full consideration, and my personal regard for this gentleman, ought not, and cannot prevent my defence of modes of planting and culture which I have hitherto defended, because, I could but presume that practices, recommended by almost all writers on the subject, must have been thus advocated from a consciousness of honest motives, based on the experience of ages; but surely not with a view of causing "the culture of the vine to be looked upon as something mysterious"—and thereby "contrived and intended to be made difficult and laborious." It is very natural for a man who has acquired experience by the practice of a particular art for many years, to imagine that there is no difficulty or mystery attending it. He is also apt to forget that it has probably cost him the labor and observation of years to come to this conclusion. Let any man of any common share of understanding undertake the practice of any art, which he has only heard or read of, and, simple though it may be, it will require a number of trials before he can reach the desired object, and find out that there is no mystery or difficulty in the practice.

That there is no more difficulty in the culture of the vine than in that of any other plant, appears evident enough from the scale of intelligence of the common vine-cultivators all over the world where it is cultivated for wine. It cannot be denied, however, that each plant has its peculiar habits, and that it grows, thrives, and is as fruitful as its nature admits, only in soils and situations particularly suited to it. The planting of trees of any sort is certainly a very plain and simple operation, depending only on the plain sense and observation of nature in her mode of proceeding; and yet there are, comparatively, but few

that perform it in the most suitable manner. The planting of the vine in deep trenches is, I believe, a general practice in Europe; though, probably not equally deep every where; and this, it is fair to suppose, is the result of experience. The first person who recommended it clearly, distinctly, and forcibly in the *Southern Agriculturist*, is George J. P. Clark, Esq. of St. Augustine. The evident intelligence and sagacity of that gentleman induce me to examine more fully and critically this subject than I had hitherto done, and the result was a confirmation of my previous views of the subject, according with those of Mr. Clark's and the experience of ages.

The transplanting of trees much deeper than they originally grew, certainly "is a departure from the order of nature;" for, "How often do we see them in their native state, put forth their roots to the surface." &c. As Mr. Geiger further very well observes: "to assist nature and not to depart from, is in my view the correct course." This is and has always been the object of the most eminent cultivators, and they have only differed as to the accuracy and depth of their alterations on nature's various processes, by which the clearest-sighted have usually been the most successful. A judicious follower of nature in her operations, avails himself of her willingness to be apparently contradicted, when the opposition is really more in appearance than in reality. He coaxes her and prevails on her to yield somewhat to his convenience, and she is usually found very accommodating in such cases.

Were the vine in a state of culture similarly situated as those in a state of nature, and were the products of cultivation expected to be not greater, or superior in quality to those in the woods, the case would be very different from what we find it. We must, therefore, look into the difference of situations and the objects in view, adapt ourselves to the existing case, follow nature in such a manner as to compensate for conditions which are unsuitable to our aims, and unattainable in our circumstances. Vines in a state of nature, in the woods, grow in shady ground, which is ever covered with the decayed and decaying leaves of the surrounding trees and bushes, and the remains of all other plants that grow in their vicinity, the collection of many years. This covering retains, at all seasons of the year, a degree of moisture at least equivalent to that which would be produced by some inches of light soil kept clear of grass and weeds, and thus perfectly open to the influence of the wind and sun. The principal roots of the vines in their native state, go as deep in the earth as the nature of the soil will permit, and the upper ones run superficially immediately under the loose bed of vegetable matter that covers the ground. If you clear the ground, cut away all the trees, bushes, and all the other vegetables but the vines, and keep it clear of grass and weeds, the effect will be that the superficial roots of the vines (except the large ones which afterwards sink deep in the ground) will perish, or, if not, will not furnish the vine with its accustomed quantity of moisture for its nourishment with its usual regularity. In wet weather they will furnish a superabundance, and in a long drought none or scarcely any. The consequence of this must necessarily be that, if the plant does not perish, it suffers and languishes till it has accommodated itself to its new circumstances. Many experiments have proved to me that this is the result. The vine (some few delicate kinds excepted) is a very hardy and vivacious plant, and it readily soits itself to any situation that does not too violently oppose its habits. Make a trench three or four feet deep, less if you come to a stiff clay, cover the bottom of it with soil, from the surface mixed with a well rotted vegetable compost, and in this plant good, well grown vines from two to six years old with their roots as entire as practicable; fill the trench only to about eight to twelve inches, and they will certainly grow well and scarcely feel the effect of their having been transplanted. The greater abundance of water that will thereby be thrown

to the roots will greatly promote the growth. Let the trench be gradually filled up, in the course of about three years, with light sandy soil, and they will be gradually accustomed to this depth, and suffer no rot to remain within this depth from the surface; but cut them away every winter at the time of pruning. The consequence will be that the vine will depend on its roots, which are deep in the soil, and where the supply of moisture is most regular, never very scanty; for a severe drought is seldom or never found to reach the depth of these roots, and never too abundant; for, water in the longest spell of wet weather, reaches to this depth but slowly and gradually. It may be said that there is some trouble attending this mode of planting; but it must be recollected that when it is done, it is for several hundred years, and that a good thing that lasts so long is not too dearly bought by a little extra trouble. The vine is very seldom, if ever, seen to suffer from drought. Its deep roots pump the moisture from far below the surface, and its abundant leaves imbibe it from the vapors of the atmosphere, which they probably condense by their coolness; so much so, that in the driest weather, when every plant in its vicinity is destitute of dew in the morning, a drop of it may be seen at every point of the vine leaves.

Let us now contrast the effect produced by the shallow planting and the retaining of the surface roots. The lower roots in this case will still tend to go deep according to the nature of the soil, and, as long as the moist season lasts, the vine will grow with very great vigor. The upper roots will furnish the plant with a great abundance of food; but when the drought comes severely, the vines will have to depend almost solely on its lower roots which are not themselves deep enough to be within the reach of a regular supply of moisture; but are affected more or less directly by the weather; whereas the upper roots that run horizontally near the surface, and which in wet weather used to furnish the vine too great a supply, are now left in an almost perfectly dry bed of earth, and exposed to the scorching sun. The quantity of roots being thus divided between an upper and a lower tier, the latter must, of course, be much smaller, and inefficient than must be the case when the upper tier is suppressed, and the strength of the whole, yielded to the lower. Any one must judge *a priori*, that such a state of things must be opposed to the welfare of the plant, and most particularly to that of its fruit. It must be here observed, that very great vigor of growth in the vine, and indeed all fruit bearing-trees, is unfavorable to the abundance, perfection, and richness of the fruit. And this brings me to notice the principal cause of the rot in grapes.

The grape, like all other fruit, is beset with myriads of enemies who prey on it; and Mr. Geiger is certainly right in accusing insects of causing great havoc in vineyards, whether by their eating, or still worse, by depositing their eggs either within or on the surface of the fruit, by which a kind of rot is induced. It is not merely one kind, but numerous kinds of insects that commit these injuries. But numerous as are these enemies, there is one much more formidable that causes a destructive rot that is even beyond the capability of the insect; though they be in countless myriads; and this dread enemy is nothing else than water, when it is too abundant. The injury done by insects is partial; but that caused by the other is, under certain circumstances, the almost total destruction of the fruit. In the first place, when much rain falls during the time when the vine is in bloom, it occasions what is called in French, "*coulure*," that is, the flower is blighted by the pollen of the stamens being washed away which prevents the impregnation of the fruit. It is very difficult to find an effectual remedy for this, practicable on a large scale. The temporary covering of the vine will do much, and the ringing of a branch of it will sometimes have the desired effect by hastening the blossoming of the branch thus operated on. The rot always takes place

when, after a long drought, a great glut of rain happens; and this is very frequently the case from the nature of our seasons. We have generally a long and severe drought in the beginning of summer, and this is most usually followed by very abundant rains. The vine, which has been allowed to retain its superficial roots, and has not, therefore, attained as much depth with its other roots as it would otherwise have done, has been, during the drought, but scantily supplied with moisture by its roots, the upper ones being roasted by the sun and drying wind, and the lower ones not only are not deep enough, but they are also too feeble and inadequate to a full supply; and if the plant has not suffered much during that time, its luxuriance has been checked. The upper roots are very dry and thirsty, and when the rainy season comes, they furnish the vine with such an abundance of water, that the fruit is filled with too crude a juice and it rots. That this is the case is evident from the rot always appearing extensively, invariably under such circumstances, and that vines so situated as not to be exposed to take in too much water, seldom or never rot. The vines planted in paved yards in towns, where the rains that descend so plentifully run off and do not sink in the earth, but in a comparatively slight degree, are seldom, if ever, affected by the rot. Such as are growing in small gardens in towns, where they are surrounded by houses and streets, by which most of the rain that falls runs off, are in proportion to these circumstances exempt from the rot. Vines planted deep, and whose surface roots are yearly suppressed, do not suffer so much from the drought; for they are supplied from a depth unaffected by the drought, and in the rainy season, the water from the clouds reached their roots slowly and gradually, and the bad effects produced in other circumstances are not as much weakened. The observation of another fact tends greatly to corroborate this view of the case. When vines that are of a bearing age are transplanted, they usually bear some fruit the first year, if they have been planted with any care at all. The grapes produced under these circumstances are seldom, if ever, affected by the rot. The cause is evidently this, that though the vines are dug and planted ever so carefully, they have nevertheless lost much of the roots, particularly the small ones which are as the mouths of the plant by which the moisture is chiefly supplied to it. I say chiefly, because the leaves also furnish a considerable supply. Now the leaves also of a vine thus circumstanced are greatly less numerous than usually. The supply of moisture in these cases is very considerably diminished, and the fruit is, therefore, not affected by the rot.

It appears to me, sir, that the above reasons are sufficient to defend the practice of deep planting, and that if, in this, I err, I do so in company with the best authorities on the subject, and not without having, at least, some plausible reasons to advance in my defence. That men differ in opinions and even as to matters of fact, is, I conceive, an advantage; for discussions lead to truth, and the attainment of this is certainly my sole object. It may be thought by many that this subject is uninteresting; but to such as may think so, I will ask if Mr. Geiger's last crop of six thousand five hundred gallons of wine, the product of very poor, and in other objects, unproductive lands, does not show it to be a matter of the utmost importance in every point of view, moral, political, economical and pecuniary.

If you think, Mr. Editor, that the above is worthy of a place in your valuable periodical, I beg you will insert it as early as convenient; for I have delayed it too long, and, I assure you, my zeal for this object has rather increased with my years, and I still think that the culture of the vine in these southern states will prove a blessing to them, and that the sooner such an object is attained the better.

I am, very respectfully, sir,

Your obedient servant,

N. HILBEMONT.

(From the National Intelligencer.)

LARGE HOLLY TREE.

Messrs. Editors:

June 23, 1833.

Taking a walk with some friends a few days since in Stafford county, Virginia, we came across a large and elegant green tree, which we were told was a holly. It seemed almost incredible, from its size, as the holly, though a native of America, rarely attains to more than a foot diameter through the trunk. Upon approaching, we found it to be the true American holly, or *Ilex Opaca*, which, measured at two feet from the surface of the ground, was seven feet six inches in circumference, or more than two feet in diameter.

This tree is situated immediately on the new mail road from Potomac Creek to Fredericksburg, and but a few yards from the present road, about a half a mile from the landing, and is well worthy of notice, as I have never heard of a holly growing to such a size in this country. Yours, respectfully, H.

(From the Alleghanian.)

TO PREVENT BUGS FROM DESTROYING VINES, &c. MR. EDITOR:

In your remarks of the 19th ult. I noticed recommended as a preventative of bugs, &c. destroying vines, plants, &c. spirits of turpentine and water sprinkled on the ground around them. But experience has taught me a plan, which I esteem more cheap and effectual; as those insects injure vines chiefly at night, and early in the morning, for as soon as the sun rises (if the weather is clear) they betake themselves to adjacent shades, where they remain until night again returns, when they also return to their work of destruction. To destroy these insects, kindle a number of small fires in the lot, contiguous to the vines at night, and they will fly immediately into them; rich split pine is preferable to any other material. The above plan was discovered by having occasion to go into a garden at night with a lighted candle, when some of them were seen to fly into the blaze; this led to the above experiment which proved effectual on the first trial. The darker and warmer the night, the better. But if others collect, as is frequently the case in a few days, repeat the fires as above, and you will certainly preserve your vines.—The season having now arrived, when attention will be paid to that species of horticulture, I have thought proper to give this receipt, which you have liberty to publish, if you choose. A FARMER.

RURAL ECONOMY.

(From the Repertory of Patent Inventions.)

METHOD OF OBTAINING CREAM FROM MILK.

A process of divesting the milk of its component portion of cream, to an extent hitherto unattainable, has been effected by Mr. George Carter, of Nottingham Lodge, and is thus detailed by that gentleman, in a paper presented to the Society of Arts:—A peculiar process of extracting cream from milk, by which a superior richness is produced in the cream, has long been known and practised in Devonshire; this produce of the dairies of that county being well known to every one by the name of "clotted," or "clouted cream." As there is no peculiarity in the milk from which this fluid is extracted, it has been frequently a matter of surprise, that the process has not been adopted in other parts of the kingdom. A four sided vessel is formed of zinc plates, twelve inches long, eight inches wide, and six inches deep, with a false bottom, at one-half the depth. The only communication with the lower compartment is by the lip, through which it may be filled or emptied. Having first placed at the bottom of the upper compartment, a plate of perforated zinc, the area of which is equal to that of the false bottom, a gallon (or any given quan-

tity) of milk is poured (immediately when drawn from the cow) into it, and must remain there, at rest, for twelve hours; an equal quantity of boiling water must then be poured into the lower compartment, through the lip; it is then permitted to stand twelve hours more, (i. e. twenty-four hours altogether,) when the cream will be found perfect, and of such consistence, that the whole may be lifted off by the finger and thumb. It is, however, more effectually removed, by gently raising the plate of perforated zinc, from the bottom, by the ringed handles, by which means, the whole of the cream is lifted off in a sheet, without re-mixing any of it with the milk below. With this apparatus, I have instituted a series of experiments; and as a mean of twelve successive ones, I obtained the following results—four gallons of milk, treated as above, produced, in twenty-four hours, four and a half pints of clotted cream, which, after churning only fifteen minutes, gave forty ounces of butter—four gallons of milk, treated in the common mode, in earthenware pans, and standing forty-eight hours, produced four pints of cream, which, after churning ninety minutes, gave thirty-six ounces of butter. The increase in the quantity of cream, therefore, is twelve and a half per cent. and of butter upwards of eleven per cent. The experimental farmer will instantly perceive the advantages accruing from its adoption, and probably his attention to the subject may produce greater results. I shall feel richly rewarded, if, by exciting an interest on the subject, I can produce any the slightest improvement in the quality or mode of producing an article, which may properly be deemed one of the necessities of life.

(From the Family Lyceum.)

PLEASANT AND USEFUL.

Some people are in the habit of thinking that nothing can be pleasant, that is of use. This is a very mistaken idea, for to a rightly cultivated mind, the pleasure arising from any object, would bear some proportion to the usefulness of that object. In fine, we should strive to make every thing we engage in, however trivial, whether for relaxation, or for the diversion of disagreeable feeling, as beneficial to ourselves as possible. This principle should be acted upon in all our arrangements. If, for instance, trees are to be planted by the road-side, to give beauty to the prospect, and shade to the traveller, those trees might be of great use if they were properly chosen. In some places in Europe, thousands of poor people are supported by the culture of silk, the worms being fed from public trees. Now if our roads were shaded by mulberry trees, the traveller would receive all the benefits that could be derived from trees of any sort, and the condition of hundreds of poor people would be rendered comfortable. By a little attention to this principle, of rendering every thing as useful as possible, our happiness here would be greatly increased. A gentleman, who died at Amsterdam some years since, struck with the correctness of this principle, bequeathed two thousand florins to a benevolent society, on condition, that two fruit trees of full growth, should be planted over his grave, the fruit to be publicly sold by auction every year, in order to prove, that even the receptacles of the dead may be rendered beneficial to the living.

EXTRAORDINARY FECUNDITY.—An ewe, of the Down and Leicester breed, belonging to Mr. Walker, of Islip, in this county, brought forth two fine lambs, and on the Friday morning following, the shepherd was surprised at finding two more lambs by the side of the same mother, all four likely to do well.—*Oxford (Eng.) Herald.*

An ewe, the property of Mr. Milliner, near Newport, Monmouthshire, yeaved four lambs, all of which are doing well.—*Sherborne (Eng.) Journal.*

BAKEWELL SHEEP.

The Subscriber has become agent for John Barney, Esq. for the sale of his celebrated Bakewell Sheep.

The stock now on hand for sale, is the following:

Eight or ten EWES, of good age and quality, at prices from \$40 to \$50.

About the first of September next, I shall have from the same flock six or eight Rams of this year's stock. Price \$50 each.

I shall have about the same time, from the flock of another celebrated breeder, a few Ram lambs—half Bakewell and half Southdown. Prices from \$30 to \$40 each. Address. I. I. HITCHCOCK, American Farmer Establishment.

DEVON CATTLE.

For sale by the Subscriber, one Devon Bull, ten months old; a handsome and promising calf. Price \$100. Also, a very beautiful and valuable Devon Heifer, two years old. Price \$175.

I. I. HITCHCOCK,
American Farmer Establishment.

DURHAM SHORTHORN CATTLE.

I have for sale the following fine animals:

One full blood Bull, nineteen months old, by Gloster, out of a first rate full bred cow. He is not above middling size, but is a very beautiful and perfect animal. Price \$250.

One full blood bull, two years old—a very fine animal. Price \$250.

One full bred Heifer, two years old, now springing, but the calf will not be valuable, being (accidentally) by a common bull. She is a very fine Heifer, and will be sold for \$225.

Less than Full Blood.

One Bull, three years old, fifteen-sixteenths Durham; has been pronounced by good judges as fine an animal as was ever in the United States. He would be worth twice the price now asked for him if he had the other sixteenth of Durham blood. He will be sold for \$300.

One Bull, fifteen months old, from good stock, seven-eighths Durham. Price \$225.

One Bull, three years old, half blood Durham, a very handsome animal, and from good stock. Price \$150.

One Cow, eight years old, seven-eighths Durham, a fine breeder, and now in calf by a full blood bull. Price \$100.

Three Milch Cows, half blood Durham, very good milkers, and of good size and form; calves from two to six weeks old. They will be sold for \$50 each.

I. I. HITCHCOCK,
Amer. Far. Establishment.

TURNIP AND MILLET SEEDS.

J. S. EASTMAN has in store prime fresh large White, Flat, and Red Top Turnip Seed, and fresh Millet Seed. Also seed Buckwheat, together with a general assortment of Garden Seeds and Harvest Tools, and Agricultural Implements generally. Also Fox & Borland's Patent Threshing Machines, with spring conveyers. July 12.

WANTED,

All kinds of GRASS SEED, for which a fair price will be given, by I. I. HITCHCOCK, American Farmer Establishment.

LINNEAN BOTANIC GARDEN AND NURSERIES, Flushing, near New York.

WILLIAM PRINCE & SONS announce to all the proprietors of Nurseries, and to those who propose to establish new Nurseries, that they will furnish articles desired at a liberal discount, and at a credit that will afford ample time for profitable reimbursement. We wish also to make known to all vendors of Seeds, or to those who desire to undertake such business, that we will furnish every variety of Vegetable, Field and Flower Seeds in quantities, at very low rates and a liberal credit. The Seeds possess the advantage of being raised under our own observation, or, when imported, of being tested to our satisfaction.

The assortment of Turnip Seeds alone consists of 27 varieties, including Dale's New Hybrid, the Yellow Altringham, and all other new and choice varieties. In the Catalogue of Seeds will be found many entirely new and very choice varieties, which have never before been offered to the public. The accuracy and vitality of the Seeds furnished by us are expressly guaranteed.

Bulbous Flower Roots, Dahlias, &c, which are easily transported, and generally vended in a dry state at the Nurseries and Seed Stores, can be supplied to any extent, and at rates that will afford a large profit to the vendor.

Every person already engaged, or who desires to engage in the sale of the above articles, will, on application, receive all the information, requisite to the object in view, and such an establishment ought to exist in every town in the union.

The New Catalogues, with reduced prices and extensive additions to every department will be forwarded to all applicants, and the present period is particularly eligible for forming arrangements in anticipation of the fall business.

N. B. It is desired that the applications be made direct per mail.

TURNIP SEED, BUCKWHEAT, &c.

400 lbs. White Flat and Red Top Turnip Seed.

100 lbs. Ruta Baga or Swedish do do

The above is of the present years' growth and raised under the immediate superintendence of Robert Sinclair, whose long success in raising this article warrants us in recommending it with the greatest confidence.

Also, Early White Dutch Tankard.

Yellow Bullock and Yellow Stone Turnip.

200 lbs. Fall Radish Seed, consisting of White and Black Spanish, Long White Summer, &c.

100 lbs. prime London Early York Cabbage Seed, Early George, Green Savoy, Flat Dutch, and many other kinds suitable for Fall Sowing.

IN STORE:

50 bushels Seed Buckwheat.

100 bushels Herds grass.

50 bushels Tall Meadow Oat Grass.

200 lbs. Canary Seed.

1500 lbs. Yellow Locust Seed.

150 lbs. Yellow Mustard Seed.

WANTED.—Clover, Timothy and Orchard Grass Seed, for which the highest price will be given. July 13.

SINCLAIR & MOORE.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Scythes, Grain Cradles, Scythes by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox & Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET—Very little variation in prices has occurred. The new wheat that has reached the market met a ready sale at an improved price, which we quote. The price of Howard street flour, from wagons, fluctuates, and is altogether regulated by circumstances. The general price paid, however, is \$5.62 $\frac{1}{2}$.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 452 hds. Md.: 174 hds. Ohio; 8 hds. Ken. and 2 hds. Vir.—total 636 hds.

CONTENTS OF THIS NUMBER.

Editorial; Large Radishes; Very early Green Corn —List of Premiums offered by the Horticultural Society of Maryland for Fruits, Vegetables and Flowers, during the ensuing year—Shearing Sheep—Foreign Markets—Prize Essay; on Agriculture in Virginia, by C. W. Gooch, of Henrico County—On Transplanting Poppies and Lupins—Letter from John Willis, giving an account of his Great Grapevine—Observations on the Planting of the Vine and Rot in Grapes, by N. Herbemont, of Columbia, South Carolina—Large American Holly Tree, *Ilex opaca*—To Destroy the Bugs that injure Vines, &c.—Improved Method of obtaining Cream, as practised in Devonshire—What is Useful must be Pleasant—Extraordinary Fecundity of Sheep —Prices Current of Country Produce in the New York and Baltimore Markets—Advertisements.

The American Farmer,

Edited by GIDEON B. SMITH, is issued every Friday.

TERMS.

1. Price five dollars per annum: due at the middle of each year of subscription, provided that no balance of a former year remain unpaid.

2. The manner of payment which is preferable to any other for distant subscribers, is REMITTANCE BY MAIL OF CURRENT BANK NOTES; and to obviate all objection to this mode, the publisher assumes the risk.

3. Subscriptions are always charged BY THE YEAR, and never for a shorter term. When once sent to a subscriber, the paper will not be discontinued (except at the discretion of the publisher) without a special order, on receipt of which, a discontinuance will be entered, to take effect AT THE END of the current year of subscription.

4. PRICE OF ADVERTISING.—One dollar per square, and in the same proportion for more than a square, or more than one insertion.

DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "I. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, JULY 19, 1833.

ROBBERING GARDENS, ORCHARDS, &c.—The practice indulged in by boys, and encouraged too often by parents, of entering gardens and orchards and robbing them of fruit, flowers, &c. has become a most serious evil in the vicinity of Baltimore, and we wish particularly to call the attention of parents and guardians to it. We have occupied a considerable garden with fruit trees in it, for many years, and can assure the reader, that while the evil alluded to continues, we consider the existence of that trees in our garden, as a misfortune. On the Sabbath, particularly, it is necessary to keep a continual watch, from the time the fruit is formed, till it is gathered, or the boys will be sure to carry it all off. This is the case also at night, and more or less every day in the week. What little fruit is at last secured, therefore, costs more than it is worth. The loss of the fruit is not all. The breaking of fences, and trampling the garden, or crop in the field, necessarily incident to it, are fully as detrimental as the robbing of the fruit. Many foreigners, also, commit these depredations, supposing, as they say, that, *this being a free country*, all fruit is free to them. We were actually told by a foreigner some time since, whom we caught carrying off about a peck of our best fruit, that he thought in this country all fruit was common property. Now, so long as this thieving disposition of the boys, (of I and young, large and small,) and this mistaken notion of foreigners, continue, it will be impossible for gardeners in the vicinity to supply us with fruit. How strange it appears, upon reflection, that boys can conscientiously *steal fruit!* They would be horror-struck at the idea of being supposed capable of stealing a "fippenny bit," and yet never consider that the fruit they are taking is just as much property as the money, and indeed, more so, because it is the property itself, while money is the mere representative of it, and is freely given away for the merest trifles. Fruit is as much the property of the owner as is his horse, or his cow, as much so as is the furniture made by the cabinet maker, or any other article made by a mechanic. It is, therefore, just as criminal to steal fruit as it would be to steal a hat or a watch, or even the money from the drawer of the storeroom par. But with people of common sense it will be needless to argue this point—they cannot be mistaken on a question so clear; if they have doubts let them become the possessors of fruit trees, and their doubts will vanish. In the northern states laws have been passed particularly for the suppression of this evil, and there it is very fast declining. We think our laws in this respect, should be modified to meet the contingency; but we would prefer seeing it accomplished by public opinion, and for this purpose we have penned the present article. To remove all doubts as to the law in the case, it has been determined by a few fruiters, to prosecute the boys and their parents and guardians, and also the foreigners, both in the criminal court for stealing, and in the civil court for trespass, until the evil in their case shall be removed; and it is desirable, that parents, guardians, masters of apprentices, and all others concerned, be put upon their guard, for they may be assured, that the full extent of the law will be enforced without respect to persons.

We have thought it advisable to call the attention of the citizens of Baltimore to the subject in this way, that they might take measures to save themselves and families from the consequences. It is particularly desired that all the city papers will copy this article with the same view.

It is estimated that the farmers of the upper counties of Virginia, have lost 300,000 bushels of grain by the late freshets.

No. 19.—Vol. 15.

(From the Family Lyceum.)

BREAD MAKING.

The business of making bread is not enough attended to in our country. The yeast is too often not perfectly sweet, and when it has become sour, alkaline substances, as saleratus, or pearlash, or soda, do not restore it to its original fitness for the process of fermenting the dough. Another defect is, that the dough when put into the oven, is frequently not enough, or too much fermented, the consequence of which is, that the bread is rather clammy or sour. Another, and almost universal defect is, that the bread is not baked enough. The thickness of the loaf may be too great for the heat of the oven; or the heat may be so great as burn or crisp the outside of the loaf before the inner parts are done.

The whole vegetable kingdom is composed of three simple elementary substances, viz: oxygen, hydrogen, and carbon. Of these three starch is composed. And starch constitutes a large part of most grains, and many roots, into some of the grains, especially wheat, and in less quantities of rye, another substance, entirely unlike starch, enters. This is called gluten, which is also composed of oxygen, hydrogen, and carbon.

The starch and gluten composing wheat can be easily separated, either in grain or flour. The starch is soluble in water, and the gluten is not; consequently, if kernels of wheat be retained in the mouth for a short time, the starch will be dissolved and removed, leaving behind the gluten. Or if a gill of wheat flour be put into a cup, and exposed to repeated washings, pouring off the water after it is applied, it will gradually dissolve, and carry off the starch from the flour, leaving the gluten by itself. The gluten is unlike starch in being insoluble in water, but it is tenacious and elastic resembling India rubber.

To the gluten we are entirely indebted for light bread. The flour of India corn, rice, potatoes, and many other vegetables, though they may be used for bread, can never be raised so as to make light bread. In the process of fermentation in bread, carbonic acid is formed, which is retained only by the gluten, the starch permitting it to escape as fast as made.

The art of making bread, especially light bread, then depends upon diffusing the yeast through it equally; in other words, thorough kneading it. When that is done the carbonic acid is generated in nearly equal quantities through the whole mass, the gluten retaining it so as to render the bread uniformly light.

When the yeast is diffused unequally through the mass, some portions of the dough are raised before others, leaving parts of it unraised, or heavy, while other parts are carried so far as to become sour.

(From the National Gazette.)

TO MAKE THE POSOLE AND SACCA OF MEXICO.

Consulate U. S. A. Campeche, 18th May, 1833.

WM. P. DEWEES, M. D., Philadelphia:

Dear Sir,—You have long known, from Humboldt, that maize is the principal food of the native people and domestic animals of Mexico, and that its alimentary preparations are as numerous and various as those of rice in China and the East Indies; but you may not yet have reflected that some of the forms in which it is used in this nominal republic are worthy of general adoption in the United States, from the combined considerations of health, pleasure and economy.

I therefore recommend through you to our professional brethren and fellow citizens, both medically and morally, the two fluid preparations of maize called Posole and Saccá. Both are milky fluids obtained from dry corn, well boiled, reduced to a fine dough by a stone roller, diffused in water, and strained through a fine sieve. The corn to make Posole is boiled with lime, and at least twice as long as the corn in pure water, from which is made the Saccá. The boiled corn for the Saccá is fit for the roller when its integuments are so softened that in some grains they split

open. The corn for the Posole must be boiled until its integuments are nearly consumed and the eyes separated by the lime. The soft grains of both are converted into dough on a slightly concave surface of a stone having a gradual descent to the table, by means of another stone, long, rounded and tapering, analogous to the rolling pin of our bakers. This laborious process of the females I do not of course mention for imitation, and as little their easy method of mixing the dough and water with their unaided hands. But be the preparatory steps what they may, when once the fine mucinous particles of this boiled and bruised corn are passed through the strainer in the shape of a white fluid—they become as agreeable to the taste as almonds under the form of Orgeat or Almondmilk; and when sweetened with sugar or honey the Saccá may be mistaken for milk drawn from the cow. As in tea, coffee, and chocolate, so in Posole and Saccá, some skill is requisite in the maker; and I therefore advise you not to form a decided opinion of their merits on a few trials. When medically presented, the physician will, of course, select the limed Posole, or the pure Saccá, according to the state of his patient's system or alimentary canal. A case of protracted intestinal hemorrhage in a lady, is now getting well under my care without any other remedy than lime water and milk, alternated with Posole as both food and medicine.

In introducing the Saccá to American society, it may be presented under the anglicised name of maizeade, by analogy with lemonade. It may be confidently recommended to our citizens as a superior substitute for Swain's Panacea, Chambers' Specific, or Graham's Bread, to remedy the evils for which they are respectively extolled; and I add that the habitual use of this cheap, unirritating nourishment will do more towards checking excess in spirituous liquors than all the temperance societies in the United States.

I am, sir, very respectfully, your humble and obedient servant,

HENRY PERRINE.

RARE BIRD.—Last week a bird of great rarity in this part of the kingdom was shot by a gentleman of Boston—the water ouzel, or water creek, or water crow. It is a solitary inhabitant of the mountainous parts of Wales and Scotland, and its habits, as described by Linnaeus and Bewick, are extraordinary—assimilating a little bird that we hear the old inhabitants of this part of Lincolnshire, ascribe to the dancing parties of the roughs and reeves which were the tenants of our morasses in the East and West Fen previous to their enclosure. Bewick, says, "this species is removed from the place it has hitherto held, in all systems, among the land birds; its habits and manners are peculiar to itself. It is chiefly found in high and mountainous parts of the country, and always by the sides of brooks and rocky rivers particularly where they fall in cascades, or run with great rapidity among stones and fragments of broken rocks; there it may be seen perched on the top of a stone in the midst of a torrent—in a continual dipping motion, or short courtesy often repeated, whilst it is watching for its food, which consists of small fishes and insects. The feathers of this bird, like those of the duck tribe, are impervious to water, whereby it is enabled to continue a long time in that fluid without sustaining the least injury. But the most singular trait in its character (and it is well authenticated) is that of its possessing the power of walking in quest of its prey on the pebbly bottom of a river, in the same way and with the same ease as if it were on dry land." What is still further remarkable, this bird is not web-footed, but has the legs and toes short and strong, like those of a crow.—*Boston (Eng.) Herald.*

A writer in the New York Courier and Enquirer, thus closes an emphatic paragraph:—"Every man that has the tail of his horse cut off, nicked or pricked, should have the fore finger of his right hand cut off, and so should the operator."

AGRICULTURE.

(From the Farmers' Register.)

MEMORANDA

OF THE GENERAL SYSTEM OF CULTIVATION AND
IMPROVEMENT PRACTISED BY

FILLING LEWIS, ESQ. OF WYANOKE.

Reports of the practices and opinions of experienced and successful farmers, however incomplete, or limited in their plan, are generally interesting and instructive to those who have still to contend with similar difficulties, and are able to make use of similar means for the improvement of their lands. Independent of these general considerations, there are other circumstances peculiar to the farm of Mr. Lewis, which may cause a report of its management to be more satisfactory than might be presented elsewhere, even though equal intelligence and industry had been exercised, and equal or greater improvements made. Under these impressions, I offer the following memoranda of a visit recently made to Wyanoke, (April the 19th, 1833.) the time of which was diligently employed in viewing the farm, and making inquiries, the answers to which will be here presented. The general appearance of the land will be described as it struck upon the first view of a stranger; but the details of practice, or opinions, will be given as furnished by Mr. L. aided (when he found it necessary) by reference to the diary of his operations.

The lower part of Wyanoke, belonging to Mr. Lewis, is situated on the north side of James river, in Charles City county. The whole farm (exclusive of one hundred and fifty acres of land outside of the enclosure, principally low marsh) consists of six hundred acres of land, almost entirely arable. It is a low peninsula, surrounded by the river and a small creek, except on one side, where a straight land line forms a boundary. The whole peninsula, though nearly level throughout, is no where entirely so; but has a gently undulating surface, which serves to keep the soil abundantly dry, without there being any where enough declivity to be objectionable. The whole of the arable land was cleared long ago; and as its natural boundaries forbid an alteration of the extent of the farm, the quantity of land subjected to tillage has not varied in half a century. For this reason, the rate of improvement may be here estimated with a degree of precision that is rarely attainable on other farms, where new clearings or other circumstances have frequently served to alter the extent of land cultivated. Wyanoke is altogether of that class of low lands which are found at intervals along the tide water of James river—which seem to have been formed by the alluvion of the river, but which formation could not have taken place, unless the water had then both a volume and rapidity very far exceeding what now exist, and a long continued elevation withal, twenty feet higher than has ever been known. Such an origin, apparently, had the fine lands of Curle's neck, Shirley, Berkley, Westover, Flower de Hundred, Brandon and Sandy Point, and various other tracts, which, notwithstanding all the existing diversities of soil, and of elevation, maintain a general resemblance. Wyanoke stretches out so as to form an angle in the course of the river, and the many depressions in the land extend through from west to east, and nearly parallel to each other, seemingly as if the river had passed over in its direct course, forming the land by its sediment, and leaving in these depressions the channels or traces of the strongest currents. The upper or western side of the land is the highest, and the elevation gradually increases through the adjoining land, (Dr. Minge's,) which is of the same apparent formation and general character. But contrary to what might be expected from such natural causes, the upper and most elevated lands are the most argillaceous, and the eastern and the lowest extremity of the peninsula, is a silicious sand, of which

the particles of course are much heavier. This lower extremity has but a few feet of elevation above the highest tides; and the depressions are there low enough to be often covered by the tides, unless where protected by short dykes. The few and narrow strips thus injured or lost, form the only unproductive or waste land within the mass of arable. The western end, which is generally the highest, may be called a good loam of medium texture, equally removed from adhesiveness and looseness. The lowest and some other parts are very sandy and loose in texture, and the great body of land is of different grades between these two extremes. In its impoverished state, and when under tillage, a great part of the farm in dry weather might suffer injury from the force of high winds.

The general fertility and peculiar value of the low lands, referred to above, are well known. Lower Wyanoke seems to differ from all in being more sandy, and until improved, was also much poorer, than the greater part of those lands. Enough still remains unimproved to indicate the general quality of nearly all the farm in 1794, when Mr. Lewis became its owner, and perhaps long after. A considerable space, which has never yet been limed, now appears even more unproductive than Mr. L. estimates its probable yield; viz: fifteen bushels of corn or eight of rye. Such poor lands he finds more profitable in rye or oats, and therefore does not sow in wheat; but supposes it might bring five or six bushels to the acre. The natural growth now on it is very meager, and throughout is in part formed of sheep sorrel and *hen's nest* grass. This piece is very level, and has well improved ground lying alongside. It is rather more sandy than the average of the farm. Except for the reddish brown color of this and the other unimproved land, there is no perceptible indication of its having been rich in a state of nature, which Mr. L. supposes was the case with the whole of Wyanoke, though all was impoverished before he first knew the farm. All the spots that have not been limed (and they are in various places) show a considerable growth of sorrel—and it appears in smaller quantity even in many places that have been limed, thus proving sufficiently the original suitableness of the soil to that weed. The reddish brown color belongs to all the land, being the darker where most improved. The subsoil is not very different from the soil, but is more sandy. No clay any where.*

It is a very general opinion in Virginia, that sandy soils are greatly inferior to clay soils, in their capacity

* Two samples of soil were selected to ascertain by subsequent examination the actual proportions of silicious sand contained. The land from which one sample was taken was considered by Mr. L. to be of medium texture, compared with the whole farm—had been limed at his usual rate some years before, as well as manured, and now supposed to be capable of yielding thirty-two or thirty-three bushels of corn, and afterwards, fourteen or fifteen bushels of wheat to the acre. The other sample was chosen to show the texture of the lightest soil forming any considerable part of the whole extent of the farm. The results obtained were as follows:

1000 grains of the medium soil, yielded

825	—	sand, mostly coarse, and almost none very fine.
161	—	fine clay, &c.
11	—	lost in the process of separation.

1000 grains of the lighter soil, yielded

873	—	sand, still coarser than the other.
122	—	fine clay, &c.
5	—	lost.

Much of the sand of both samples was tinged with the color of rust of iron. The clay was brown, slightly inclining to red. No carbonic acid gas could be expelled from either sample, and therefore, no carbonate of lime was present.

for receiving durable improvement, and yielding the most valuable products and profits to the cultivator.— This opinion has probably grown out of the facts, that nearly all of our most valuable lands are loams of different degrees of adhesiveness, and that our sandy soils are almost always poor, and of little profit to their owners. Another opinion, still more extended, and indeed almost universal, is that though rich sands may be even the best of corn lands, they must be comparatively worthless for the production of wheat.— The belief long entertained that both these opinions are quite erroneous, formed another inducement to present a report of the farm, which furnishes abundant proof that the mere deficiency of clay does not prevent a soil reaching the highest value. Wheat requires a stiff soil to yield the greatest possible product—but such lands require so much labor, and their management depends so much on the season and weather, that their crops of wheat are often less heavy, and still oftener less profitable, than on good sandy soils, where the friability of texture causes tillage to be far cheaper, and the alternations of wet and dry seasons have a comparatively but little effect in injuring the crop, or obstructing tillage. The crops of a sandy soil, or which the maximum product is twenty-five bushels of wheat, would generally be heavier, and certainly would give more average clear profit, than those of clay soils that might bring forty bushels, under the most favorable circumstances. But it is time to bring forward in support of this position, opinions and practice that will be justly deemed of much higher authority, than any deductions or reasoning of mine.

Rotation of Crops, and general plan of Cultivation. The farm was formerly kept by Mr. L. under the three field rotation, 1. corn—2. wheat—3. at rest, under the spontaneous growth of grass and weeds, and more or less grazed. At that time, and long afterwards, this rotation was the mildest in use in lower Virginia. Since 1816, his rotation has been 1. corn—2. wheat on all good land, and oats or rye on the unimproved and poorest—3. clover, mowed—4. clover, grazed. Clover, however, has occupied no more land than had been previously limed. Field peas, which always follow the new applications of lime, take a part of the field of the fourth year; and another smaller part is under turnips. Formerly, one hundred and ninety acres, or one-third of the farm, was every year under wheat, except such parts as were quite too poor—and the average crop was less than one thousand bushels. Now one hundred and forty acres make a field, and the unimproved or poorest parts (usually about forty acres) being in rye or oats, only about one hundred acres are put under wheat, and the annual average crop is now more than doubled. Last year, 1832, when only ninety-eight acres were in wheat, the crop was over two thousand bushels. The present average product of all the land usually put in wheat, is supposed to be twenty bushels—and the corn from the same land the previous year is thirty-five bushels or more.

Though Mr. L. has been, since 1794, attempting to improve his land by using putrescent manures in unusually great quantities, and by his well known careful and judicious general management, still the great improvements made have commenced within the last twelve years, during which time he has been regularly applying lime, and has now given that manure to about three fourths of the land. He had made small experiments with lime as long as six years before, when its use was unknown in this part of the country, except in small experiments. But for the last twelve years, like some other neighboring farmers, he has gone as fully into the practice as the supply of shells, and the disposable labor of the farm would permit. Lime first enabled him to make clover a field crop. Before, it could not be produced with any certainty or profit, except on the richest lots around the houses, which had the best preparation and every care bestowed. It is now an abundant crop

wherever his lime and the sub-equent covering of putrescent manure extend.

The quantity of stable and farm pen manure prepared and applied are unusually great, even considering the abundant supply of materials, compared to the general usage. But no other means for furnishing vegetable substances to the soil are used, no green crops ploughed in, nor the entire growth of grass left any where to rot upon the land. It is preferred to pass every putrescent material through the stables and cattle yards. In this respect the practice of Mr. L. differs essentially from other successful improvers of the soil. His green or meliorating crops of clover, peas, &c. are partly secured for dry food, and the balance consumed by live stock in the field. He has tried marsh mud, (to which his access is very easy,) but found it not worth the labor. It was of a kind composed principally of decayed vegetable substances. Naked fallows for wheat are rejected; and even wheat on clover lay, as being on the whole, less profitable on such land than wheat after corn. This decision is not influenced by a belief that the former practices would be injurious to the soil. He is not satisfied of the correctness of the common opinion, that the soil is impoverished by exposure to the sun.

Burning and applying Oyster Shell Lime.—Close kilns with walls of brick or stone, have not yet been used to burn oyster shells for manure; and until fuel becomes more costly than the additional transportation of the lime, it will be cheaper to use wooden kilns. What are commonly called lime kilns are merely heaps of wood and shells, built up in a somewhat cubical form, by which the burning is imperfectly performed at great expense of fuel, though without much trouble. Mr. L. burns his shells in the following manner. A pen of sixteen or seventeen feet square, is built of round green pine logs, (notched where they lock, so as to come as close together as their form will allow,) and with a floor of similar logs, chinked with smaller pieces, so as to prevent the shells dropping through. The bottom logs of the kiln are laid on four corner blocks, of twelve inches, so as to leave a vacancy of twelve or fifteen inches between the earth and the bottom of the floor, which is to be packed closely with dry wood. The walls of the pen are raised about nine feet; and about one hundred logs of six to eight inches through (which these now put up seemed to be) usually serve for the floor and side walls. The shells are thrown in, and in layers of different degrees of thickness, according to their order, and separated by thin layers of pine wood, cut eight feet long, and split to the usual size for fuel.—The size of the last kiln burnt by Mr. L. according to his memorandum book, was as follows:

Kiln seventeen feet square and nine feet high, inside measure.

The lowest bed of shells eight inches, (he thinks it might as well have been twelve inches.)

The second bed of shells 12 inches.

“ third “ “ 16 “

“ fourth “ “ 20 “

“ fifth “ “ 15 “

“ sixth “ “ 6 “

The layers of wood between were equal, and about six inches. This kiln took one hundred hogsheds of shells, and consumed ten cords of wood in the layers, and three more of foundation or kindling wood. The kiln should be fired in calm weather; and if the wind afterwards rises, it should be kept off as much as possible by a screen of brush, or whatever may be most convenient.

The burning (in preference) is done in March, or as soon after as may be. The newly burnt shells are carried to the field as soon as they are cold enough, and deposited in small parcels of a measured heaped half bushel each, at distances of six yards. The field is previously ploughed, and marked off carefully in checks of six yards square. These small heaps of shells are immediately covered completely, but not heavily, by the surrounding earth being drawn over them

with broad hoes. If a heavy rain was to catch the lime before this covering, much of it would become a wet sticky mortar, difficult to manage and impossible to distribute equally. When secured in the heaps, the moisture absorbed from the earth will usually slake the lime in forty eight hours. The heaps are then cut down and mixed with hoes, and carefully spread so as to cover the field very equally. The land is then well harrowed, more effectually to distribute and mix the lime with the soil. The quantity applied to the acre is about seventy bushels of the burnt and un-slaked shells, which quantity is produced by burning six hogsheds (one hundred and eight bushels) of shells; and the same, if well burnt, will swell in slaking, to one hundred and twenty five or one hundred and thirty bushels. The lime is always put on a part of the field of the fourth year, and is put under field peas the same year. The red, or cow pea, is preferred, being considered most profitable for live stock; and as that is a late kind, it should be planted as soon as possible after the twentieth of April, that the crop may mature. Two after ploughings and one slight hand weeding serve to cultivate the crop; and its product, Mr. L. thinks, though without having made any experiment or careful estimate, usually pays the whole expense of the liming. He has the bulk of the peas gathered by hand, but not closely; and the remaining pods and vines are eaten on the ground by cattle. The peas are partly ground into meal and mixed with other food for mules, for which use they are much valued. Mr. L. has never compared the products of peas with corn on equal land, but supposes that more bushels per acre would be obtained from corn.

Mr. L. does not think that a heavier cover of lime would be much more effective. He showed the ground where an experiment had been carefully made to test this question, and which is still on trial. Three years ago a certain space marked out through equal land, was limed with a second cover equal to the first and usual quantity, which had been applied to the field four years earlier, and was followed by manure from the stable and farm yard, the year after the first liming. The field is now in wheat, and the growth excellent throughout, but unequal, and the part doubly limed is not perceptibly superior to that on either side. Still he expects a different result on a soil less light, and applied his last lime as a second and lighter dressing to the stiffest loam, in preference to the lightest land that had yet received none. He has found that the lightest soils here, and the stiffest among the clay soils of his farms in Gloucester, are neither so much improved by liming as are soils of medium texture.

The whole expense of liming has not been estimated by Mr. L. nor has the benefit from lime alone been ascertained. He always covers with putrescent manure the whole of the previous year's limed land, and sows all in clover. The durable benefit obtained from the manure in part, and the whole value derived from the clover, are indirectly the effects of the lime. The expense bears a very small proportion to the profit.—The only difficulty in liming, arises from the scantiness of the supply of shells, and the fear that they will be still more scarce, as their use extends. Small vessels now bring cargoes of oyster shells, and sell them (on board) at sixty-two and a half cents the hogsheds. The labor of landing them is an additional expense to the farmer.

Gypsum had been frequently tried on clover as well as other crops before liming, and with little or no benefit. It has not been tried since liming, but he is now about to make the experiment again.

No value is attached to the caustic quality of the lime, and indeed it is supposed to have lost that quality by exposure under the usual treatment, before the succeeding crop of peas begins to grow. Ten or twelve days are generally allowed to intervene for this purpose, between the spreading and harrowing in of the lime, and the planting of the peas. When peas were planted immediately after the spreading, their

growth was thought to show some injury from the remaining causticity of the lime. Still Mr. L. is not satisfied, that an equal quantity of mild calcareous earth in any other form, would serve as well as lime prepared by burning. Without denying the correctness of that deduction from his opinions and practice, he prefers adhering to the practice which experience has proved to be highly beneficial and sufficiently cheap. No banks of fossil shells are on his land, nor nearer than eight or ten miles distance by water carriage.

As one-fourth of the farm has not yet been limed, the general improvement by that means is still in progress, and the increase of crops may be fairly supposed to be yet much below what a few more years of the same practice will exhibit. Whatever increase of product has been obtained is almost entirely owing to lime, considering its indirect as well as its direct benefits. Without lime, there was (and could be) no improvement from clover; and all the putrescent manure used before liming, seemed merely to keep the products of the farm from decreasing. This opinion requires no stronger proof than the following table of all the crops of corn and wheat made for twenty-one successive years before liming was begun, and when the farm was under the regular three shift rotation. The fulness and accuracy of Mr. Lewis' diary, has enabled him to furnish me with this statement.

YEAR.	WHEAT. Bushels.	CORN. Barrels.	Price of corn sold.
1796	1162	516	\$3 75
1797	896	842	3 00
1798	975	650	3 00
1799	1280	661	2 50
1800	740	620	4 41
1801	1400	750	3 33
1802	1153	811	2 46
1803	910	625	4 00
1804	1150	573	5 00
1805	863	650	2 33
1806	1160	524	5 00
1807	989	650	2 00
1808	1060	646	2 33
1809	187	700	3 50
1810	1060	750	3 75
1811	1255	544	4 00
1812	905	652	3 00
1813	820	667	3 33
1814	710	484	3 42
1815	1210	448	4 00
1816	912	425	7 00
Average, 1052		630	Average.

Though this table shows much difference of product from good and bad seasons, there is no apparent average increase in the product of any one field. The crop of wheat, which stands first in each division of three years, was in every case on the field which was in corn the previous year; and in like manner for the second and third crops. Thus each division of the corn crops shows the whole product of the whole farm in corn—and the same as to the wheat, for as much of each field as was worth putting under that crop.—The fields were about one hundred and ninety acres each. When divided into four fields, after 1816, the crops of the first year were diminished, by each of the fields losing about fifty acres in extent, notwithstanding the counteracting benefits then beginning from lime. The last crop of wheat (1832) was two thousand one hundred and ninety-nine bushels, from ninety-eight acres, and eighty-eight bushels of seed. The season was good for wheat—the field is rather more productive than the general average of the four, but is not the best of them.

The crops of corn have not been so much increased as those of wheat for several reasons. The unimproved part of each field is now as formerly, always under

corn in its turn, and it may be well supposed that no increase of product is shown there; and the former impoverishment of the other land did not lessen the yield of corn so much as wheat, from the peculiar fitness of this sandy soil for the growth of corn.

Since the putrescent manures have succeeded lime, it is not supposed that their beneficial effects have been lost by time and after cultivation. It needs no other evidence than the foregoing table of crops to prove that the effect of the manure formerly applied must have lasted but a very short time.

Putrescent Manures.—About fifty head of cattle are kept, (not counting the calves under a year old,) sixty sheep, ten or eleven work horses or mules, four saddle and carriage horses, and as many hogs as will furnish about fifty annually to be slaughtered for bacon. From two thousand six hundred or two thousand seven hundred good horse cart loads of manure from the stables and littered pens (with some other putrescent matters) are usually made, besides the feed manured by naked cow pens in summer. The whole space manured already for the present corn crop, amounts to fifty four acres. The vegetable materials used as food and litter to make this manure, are the straw of the wheat crop, the stalks and the better forage of the corn, the clover from as much as can be mowed of the limed land of one field, and the coarse hay of eighteen acres of wet marshy meadow.—Leaves raked in the woods, are enough valued to be carted (when leisure permits) two and a half miles, which is the distance from the woodland belonging to the farm. Five or six acres of turnips are also made, which add greatly to the value of the manure, as well as to the food of the milch cows, oxen, &c. The winter pens for cattle are made in the field to be manured, which is always the land intended for corn. Plenty of litter is furnished, and early in January the rickling is commenced, and continued from time to time as the state of the weather and the manure may require. The stable yard has a long pit eighteen inches deep, into which the fresh manure is thrown, with the litter cleared out of the stables.—This general clearing out is not done except on rainy days, or other leisure times. When quite wet, this manure is carted from the pit, to aid in forming a rick made just without the cow pen. For this purpose, the parcels of litter from the cattle and from the horses, are laid in alternate beds on each other, two feet of the former to one foot of the latter. The ricks are built sixteen and a half feet wide, (being the width of three corn beds,) five feet high, (which lessens to three, by settling and fermentation,) and of any length that is convenient. The materials are thrown on very lightly, and the building proceeds from one end of the rick, so that each part is soon finished, after its foundation is laid. This rickling is done whenever the manure is wet enough, without much regard to the time the materials have been exposed to trampling. The ricks usually begin to ferment in forty eight hours, and in fifteen or twenty days may be carted to the field. Its texture will be then considerably softened, though the manure when used, cannot in general be said to be as much as half rotted. Poles are placed in different parts of the ricks when they are made, and by pulling them out and feeling them, the heat of the whole mass is known. By this mode of fermenting, *fire fangling*, (the white moldy appearance, so common on manure,) is avoided, and the whole rick makes good manure. The cow pen litter when used alone for manure, was always found very weak. Mr. L. thinks it proper to heap and ferment the manure, so as to break down the texture of the coarse litter, but does not approve of thorough fermentation, any more than the total want of it.*

The times of carting out the manure from the ricks, do not depend so much on their age (after having been heaped fifteen or twenty days) as upon the state of the land. When carried out, the heaps are dropped at twenty four by twenty-seven and a half feet, spread and ploughed under very carefully, and as soon as possible to avoid waste from exposure to the air. The whole job had been completed but a few days before the day of my visit, (April 19th.) The manure now making in the stables and littered pens, will be used for turnips after being ricked. Of course, the season, and the length of time will cause the fermentation to be more complete. Mr. L. does not approve of top dressing, though no actual experiment had proved the loss incurred by that practice; but supposes it may be advisable when the manure is perfectly rotted. The cattle will now soon leave their last littered pens for moveable pens on the naked land, as is the usual practice. During the summer, about five acres are dunged in this manner. The land intended to be manured by the summer pens, is ploughed first, and as much as is manured in good time is prepared for turnips.

The raked leaves are used only for the hog pens, in which they are put so thick as to prevent the hogs from rooting to the earth below. Enough of this litter is used to make about three hundred loads of manure, the quality of which is very good. The pine leaves are considered the most valuable. All the hogs are confined in pens through the winter and spring, until the clover is enough advanced for their grazing, when they are turned upon the field of the fourth year. They are now confined, and on corn feeding. Forty hogs nearly grown, in one pen at this time, are kept in thriving condition on two bushels of corn a day. Simblins are raised for hog food, and considered very valuable for that purpose. It is not from choice that the hogs are thus kept in pens, but because if turned outside of the enclosure they are often lost or stolen. The cattle and sheep have some advantage from one hundred and fifty acres of land outside of the enclosure, of which, much the greater part, however, is low tide marsh, from which the cows can get very little food, and the sheep none.

Throughout the winter the cattle are confined to their pens, except during the short time required to drive them to water twice a day. The facility of the general opinion that close confinement of cattle in littered pens is injurious, by making them both lousy and diseased, is sufficiently exposed by the good condition of the stock of Mr. L. under this treatment. The injury imputed to this cause is in fact, produced by a want of enough litter to keep the cattle dry and comfortable.

With sheep, the case is different. Though the want of suitable pasture ground for them, compels Mr. L. to pen his small flock during winter, they suffer from the confinement greatly; and many would

opposed are found on the farms of several intelligent gentlemen, all of whom are good farmers, and successful improvers. The practice of Mr. Lewis is described above. Mr. William Minge, of Sturgeon Point, leaves all his manure undisturbed on the farm yard until after harvest, when it is moved, put into large heaps, and covered with earth, to remain until used the succeeding spring on corn. Mr. John Selden, of Westover, uses the whole of his farm yard manure the spring it is made, for corn, without heaping to ferment. Mr. Hill Carter, of Shirley, leaves his manure in the yard, thickly covered with straw, until August and September, when it is carried out and ploughed in on his fallow for wheat. Mr. Collier Minge, of Walnut Grove, approves of and practices top dressing on wheat. Some other differences, though less striking than these, may be found in almost every farmer's practice; yet, each one thinks his own course the best to avoid (what all alike fear) the great waste of the enriching principles of the manure. Such opposite opinions and practices, show how much is lost for want of free communication and discussion, and that by an interchange of opinions, each individual perhaps might both receive and dispense instruction.

die, but for the succulent food furnished them in turnips. Peas are given to them also, in considerable quantities. The management of sheep which Mr. L. adopts, is not such as he deems profitable, or would recommend to others. He considers their grazing so destructive to grass, and consequently so injurious to the soil, that it causes him to keep no more than will serve for the supply of mutton and lamb for the family.

In being my object only to report the general system of cultivation and improvement, I do not enter upon the feeding of live stock, except as connected with the making of manure. Yet there is no part of the economy of Mr. Lewis' farm more admirable (as is generally supposed) than his manner of feeding, particularly as it regards horses and mules.

Preparation for Corn.—Low as is the Wyanoke land, and with a surface seemingly shaped so as not to permit much surface water to run off, very little draining is any where requisite, and cultivation with a level surface is admissible, except on some of the land so low as to be affected by the highest tides. Generally, the open texture of the soil and subsoil is sufficient to pass off all superfluous water from the surface.

Not a spring bursts out any where on the farm, and there is no need for any side ditch to cut off such oozing waters as form the greatest objection to our hilly lands. This absence of springs is one of the great advantages possessed by the cultivators of soils formed like Wyanoke. But though ridges and water furrows are not wanting to keep the surface dry, the corn land intended to receive the manure is always ploughed and tilled in five and a half feet beds, under the belief that the manure can in that manner be best secured in the soil, and less disturbed and exposed by the after tillage. Still, the manure is not accumulated in the former water furrow, when the beds are reversed; for care is taken so to spread it, that it may be dispersed as equally as possible through the whole width of the bed. The land not recently manured is ploughed flat early in the winter, the rows laid off in checks, and tilled by double shovel ploughs, and other implements suitable to the friable and yielding nature of the soil. The labor of tillage is very light, considering the richness of the land, except where wire grass grows; and even those spots are made nearly as easy to cultivate as the balance, by removing that abominable weed at an enormous cost of labor, before planting the crop. The growth of wire grass seemed the only considerable evil attendant on the numerous advantages of this farm. The sandy and rich soil now made calcareous, is as favorable as possible to the growth and increase of this plant. Mr. L. computes the labor caused by wire grass to be equal to one-fourth of the whole tillage and management of his crop of corn. His most laborious operation is conducted in the following manner. When breaking up the land in December, the ploughmen mark every spot of wire grass turf by setting up small sticks, which are provided in great numbers for the purpose. These marks are necessary, because when the soil is well turned five to six inches deep (five preferred to a greater depth) the wire grass can scarcely be seen until it begins to grow, which is late in the spring.—In the latter part of winter, and whenever the earth is fit for the operation, men dig up the long roots with three pronged hoes—such as are described and recommended by Taylor, for digging, and loading with coarse manure. These tools are made strong, and are admirably suited to taking up the wire grass. The roots which are thus obtained in great quantities, are shaken clear of the soil, heaped when dry, burnt, and their ashes scattered on the land. At this time, they are carted off and thrown into a small piece of adjacent marshy ground. The burning, or throwing away of so much vegetable matter, which also could not be entirely cleared of the rich mold in which it grew, seemed to be a waste of materials for manure, not according with Mr. L.'s general practice. But he considers wire grass roots as but a poor litter—and when

*It is surprising what different opinions are held with regard to the most advantageous preparation and economical application of farm yard manure. Even within the small county of Charles city, practices the most

he formerly tried it for manure, its life was never entirely destroyed, before it was carried out to the field to increase the stock already growing there.* Six men were engaged in this job at the time when these observations were made, and they had still ahead of them a large portion of the field thickly marked by the sticks which directed to the concealed enemy.

Mr. L. has his seed corn prepared in a manner which he finds effectual in preventing crows from eating it. They will make a sufficient examination throughout the whole field, and then move off to some other place offering better fare. The same means, however, are not sufficient to guard against blackbirds. The seed is treated in the following manner:—To a convenient quantity of corn pour hot water, keeping the corn well stirred as long as the water is pouring on. The water may be almost boiling without injury, if the corn is kept in motion. After standing in the water about twelve hours, the corn is drained by being placed in baskets, and then spread on a table. — Tar and sturgeon's oil (or train oil) are then well mixed with the corn, in the proportion of two pints of tar and one of oil to three bushels of corn. Enough quick lime is then added to cover the grain, and he fixed by the tar and oil; and finally one gill of pound-ed sulphur is well mixed with each bushel of corn.

Plant.—The quantity of seed given is on y three to three and a half pecks to the acre, generally—and only a bushel for the best, or the sun-est soil. Thicker sowing considered injudicious on s of so light. An observer riding through the fields at this time, would not suspect that so small a quantity of seed had been given, as the growth looks thick enough, as well as very luxuriant. Many parts of the field now appear as if the crop would lodge. Mr. L. supposed that some of the best spots will produce at the rate of thirty bushels to the acre. His lodged wheat is cut with reap hooks.

The land manured for corn is kept in beds through the cultivation, to prevent as much as possible exposing the manure. For the same reason, the wheat is afterwards sowed on the surface, and covered by small (double shovel) ploughs. All the other land is ploughed before sowing, with two horse ploughs, throwing several corn rows into one flat bed, and the seed is then sowed and covered with harrows. The slight covering of the seed is not supposed at all injurious to the crop. The beds formed in ploughing for wheat, are not needed (except in a few situations) to keep the land dry, but are useful to direct the sowing of clover seed.

Turnips and other Succulent Crops.—Mr. Lewis decidedly prefers turnips to any other root crop. He supposes his usual product of turnips, (without a bad season or some other serious disaster) equal to eight hundred bushels the acre. He does not believe that turnips (in this country) deserve to be considered as an improving crop, as they are held to be in England; and neither does he concur in the general opinion entertained among us, that they are extremely exhausting to the soil. To support his defence of this plant, he showed the land now in wheat, which was manured by summer cow pens in 1841, and only part of which was put in turnips, and the whole in corn the following year. The wheat on all is very fine, and perceptibly better on the part which was not under turnips; but the difference is so small, as to sustain the opinion that the injury caused by the turnips, bears no comparison to the value gained from that crop.

Parsnips and carrots are also made in smaller quantities, to furnish juicy food to milk cows, &c. after turnips are unfit for use. Carrots require much richer land than turnips. Some rich bits of orchard grass,

* A farmer on lolly land can use wire grass advantageously to lay on his numerous *guts*, where the soil has been entirely washed away. As wire grass cannot grow on very wet land, the roots if heaped in a wet pit surely would die and rot. The green roots contain much saccharine matter, and are eagerly eaten by hogs, and also by moles when thrown into the stables.

and lucerne also are kept for green feeding before clover is enough advanced. None of these crops except the turnips occupy any part of the four fields, and therefore, do not affect the general rotation, nor come within the range of my inquiries.

Postscript. A subsequent visit to Wyanoke (May the 13th) has enabled me to supply some deficiencies in the foregoing memoranda, particularly as to the management and uses of *clover*. A few years only have passed since the establishment of the fact that the profitable field culture of clover was possible in the tide water district of Virginia, except on some soils of rare and peculiar qualities. Even now, it is far from being generally known that calcareous manures (and nothing else without them) will serve to remove the general incapacity of our lands to produce clover—and will make that crop safe and valuable, even on some of our most worthless natural soils. The methods for making clover hay in the northern states, and in England, are unsuitable for us, not only because of the difference of climate, but also of our cultivation in general. When our clover is ready for mowing, we are pressed with the heaviest and most essential part of the tillage of our largest and most important crop—corn. On this account, it is not so important for us to make hay of the best possible quality, as to obtain the greatest value in quantity and quality combined, for the limited amount of labor which we can then devote to that purpose. For these reasons, as well as the very limited extension of the clover husbandry among us, I hope at least to be useful to novices in this business, by stating the experience and opinions of a farmer who has had to contend with every common obstacle to the production of this important crop.

Mr. L. saves his clover seed from the second growth (after once mowing) of the second year of the grass. The dry heads are gathered by a simple utensil, the operating part of which is merely a short piece of plank, having the end cut into a comb like form: the long slender teeth allow the stems to pass between, but break off and save the heads, which fall in pieces at the same time. The seed thus saved are not only cheaper, but they come up better than the clean seed brought for sale from the northern states. They are sown in February, and the beginning of March on the wheat land—No harrowing or other means of covering the seed is considered necessary. To distribute them at the proper rate to the acre is the only difficulty—to surmount which, the lengths of the wide beds are measured as often as necessary, to fix their extent nearly—and each seedsman scatters over a certain assigned space, the proper measure of seed. If he leaves a remnant at any one trial, he will know better how to suit his casting to the next piece of land. A flour barrel of seed in the chaff, pressed in very lightly, is equal to a gallon of clean seed, which is our usual allowance for an acre; but Mr. L. thinks that quantity too small for good sowing, and gives one and a half gallons, or one and a half barrels in the chaff, to the acre.

The next year, mowing begins early in May, for green food for horses and mules. It is generally thought that green clover is weakening and injurious to working horses and mules; and some of us who hold a contrary opinion, are yet compelled to yield to the prejudices of our overseers, that we may deprive them of the ready excuse which green clover feeding would furnish them for slow and insufficient ploughing, or poor teams. Mr. L. has a day's allowance mowed in the morning, which is thrown into small heaps as soon as it is clear of dew. This is used for feeding at night and the next morning. Two well filled horse carts are brought up every night and used at the two feedings. The long food for mid-day is always of dry fodder. Corn, as usual, is given at every time of feeding, but less is eaten, from the greater relish of the horses for the clover. So far from any injury being sustained, the horses seem to improve from the use of their green food. It should be men-

tioned, that one or two of the work horses are generally not at work, and this share of rest they have as they most need it. At other times all are at work together. The second growth is never mowed for green food, as its salivating quality makes it always hurtful.

Owing to the very succulent nature of clover, and the variability of our weather, there is much in risk in curing clover hay. With all the care that can be used, the thin leaves will generally become crisp, and fall off in the various handlings of the hay, before the large sappy stalks are enough cured to stack. If a soaking rain or even heavy shower falls, the best made cocks of clover hay will be so penetrated with wet, as to require all the trouble and loss of drying. After sustaining much loss of labor and of crop from these causes, Mr. L. has adopted a method which he has found to save a deal of labor, and on a general average, to furnish better hay. His mowing for hay goes on in any weather, except it is raining too heavily for laborers to be out of the house, or unless the earth is full of water. Three swaths are raked into one high ridge, immediately after mowing, if clear of dew, or as soon afterwards as the dew has dried off. This operation substitutes all the usual and various labors of opening, turning, putting into cocks, &c. The rows remain, taking the sun and rain, until the hay is cured, which may be in five or six days of common weather, and has been as long as ten in the worst. The surface is so burnt by the sun as to cause the row to appear to be ruined by the exposure; but the injury is only superficial, and that cover protects what is beneath. If rain comes, as usually happens, the whole row is made completely wet, but it is thin enough to dry afterwards without moving. When cured, it is thrown into small cocks, which facilitates the loading of the wagons, and also serves to air the hay, and remove any remaining dampness. If the weather is good, the hay is moved without delay to a house where it is packed away, or otherwise put into large ricks containing from 12,000 to 20,000 lbs. of hay, and which are covered thickly with straw. If the weather is threatening, the cured hay is put into small stacks until it can be put into the house. From the description of this mode of hay-making, it might well be supposed that the hay would always be bad, and generally worthless as food.—But Mr. L. has commonly made better hay in this manner, than when he used much more care and labor—and has never entirely lost any, from the worst of weather. The weather can scarcely be expected to be worse for hay-making than in 1830, yet his clover which passed through that trial, made what might be called hay of better than middling quality.* In general, the leaves

* After hearing this statement from Mr. L. I accidentally observed his memoranda of the circumstances referred to, as we were looking into his dairy for some other facts—and, with his permission, I took the following abstract, relating only to the weather and other circumstances connected with the hay-making.

1830—May 30.—Heavy rain.

June 1.—Began mowing for hay. Weather still very threatening, but no more time can be spared.

4th.—A very great fall of rain.

5th.—The earth so saturated with water, that no field work (nor mowing) could be done.

6th.—Rain threatening through the day, and at night it came so heavily, that again on the 7th no field work.

8th.—About sixteen acres of clover have been mowed, and raked three rows into one—the crop a heavy one for our land. Such heavy rains have fallen, and have driven through the clover ridges, that unless we have clear weather from this time, I fear we shall have a very indifferent crop of hay. Have been five days mowing. Weather now fair, and we are putting the hay into cocks previous to stacking.

9th.—Fine day for hay-making, since the last clearing off, but unfavorable to corn, being uncommonly cool. For five days past, the thermometer has been each morning as low as from fifty-two to fifty-four degrees in the shade.

remain on the stalks, and the greater bulk of the hay retains its green color.

Though the general plan of the rotation is to mow the clover the year after wheat, yet the mowing never extends over the whole field for want of time and labor for so heavy a job. The balance of the field is grazed.

Summer Fermented Manure. Much the greater part of the manure is made during the colder part of the year, because there is neither enough litter left, nor enough spare labor during the warmer months, to profit fully by the supply of animal matter furnished by the stables alone. The use of litter on summer cow pens would be rejected, even if it was more abundant, as a wasteful application, from the certainty of great loss from fermentation. Still some loss from fermenting bulks of manure must necessarily be suffered. When all the fermented (or ricked) manure is carried out in April, the cow pens is moved to the land intended for corn the next year, and littered; and the cattle remain there the short time that intervenes before the naked penning is begun. This litter will be too dry and too poor for early heaping; but when wet weather allows the stable dung pit to be emptied, its contents are carted to the cow pen, and a rick formed, as was before described, by using alternately layers of the two kinds of manure. This has not yet been done: but the pit was full of dung, and flooded with water from late rains. This is the proper state of things for the operation of rickling.

The scarcity of litter in the stable during summer, prevents the heat that would otherwise take place, and no inconvenience is sustained by the horses from that cause, between the times when the stables are emptied of the manure. In dry weather, the water in the pit settles to the bottom, and the upper part of the manure would suffer by becoming too dry. To prevent this, five or six holes are dug through the dung to the bottom of the pit. In these the water collects; and every morning it is thrown over the top of the manure, which is quickly done with broad paddles.

The heaping of the litter of the pens where bees and milch cows had been kept until lately, was going on, which gave me an opportunity of witnessing the great superiority of the three-pronged hoes, and three-pronged forks to our common tools, for moving coarse manure. Few, perhaps, would consider the use of these tools of much importance from any description of their advantages; but whoever sees them used for five minutes, will determine never again to heap, or load with manure, without their aid. This manure, though coarse (being principally corn-stalks) was rich from the fat animals kept on it, and the richness of their food, and was quite wet. I should expect it to suffer from *five fanging*, the effect of violent fermentation; but Mr. L. entertained no such fear. This, and the other ricks that the stable dung will help to form, will be used for turnips.

It is remarkable that Mr. Lewis' fields are now where infested with blue grass, which is the worst of plagues on most good loams, and especially after liming. It is true that this grass thrives best on soils that are both moist and somewhat adhesive, as well as of good constitution. If, indeed, it is the want of sufficient moisture and adhesiveness that prevents this grass growing on any spot here, the fact furnishes stronger evidence of the dryness and sandiness of the soil, than would be inferred from my description. Without drawing that inference, I merely state the fact.

Partridge peas, which are so troublesome in wheat crops on all calcareous soils, and more so on light than stiff, are remarkably scarce on Wyanoke; but the exemption from the ill effects of this pest will not last long, as it is increasing fast on the limed parts of the land.

11th.—Fine morning. Thermometer sixty-five degrees. Yesterday hauled to hay house twenty-five loads. This day we continue—two more loads to the house, and twelve to the stack. Next day finished the stack with seven more loads or nineteen in all."

HORTICULTURE.

THE SEASON.

IN A LETTER TO THE EDITOR OF THE AMERICAN FARMER.

Greatfield, Cayuga Co. N. Y. 6 mo 10, 1833.

The last winter was comparatively mild, the mercury in the thermometer scarcely sinking down to zero. The spring opened not earlier, however, than usual, but as it advanced, we had hot weather, at various times when the thermometer was above eighty degrees. Vegetation is in consequence, two or three weeks in advance of some other years. We had ripe strawberries on the 21st *ultimo*, a circumstance which has not occurred before within my recollection; and on the 26th *ultimo*, we had ripe cherries. In 1826, we had ripe cherries on the first of the sixth month, and that was considered a very rare occurrence.

It may be remarked that we cannot have *early fruit* without having *early varieties*. I have not the name of our earliest strawberry—the cherry was the "Early May," which though small, is delicious when fully ripe.

The difference of climate between Baltimore and this place is, probably not less than five weeks; in particular seasons it may even be greater; but this is to be understood of the spring, or of the early part of summer. Autumnal frosts scarcely occur sooner here than along the shores of the Chesapeake.

We have a fine prospect of fruit, although many of the blossom buds of the peach and of the apricot, were killed, perhaps more than two-thirds of the latter, yet the trees have a full crop. The same may be said of our plums and nectarines. Pears which set last year most remarkably thin, now promise abundance; and it is particularly gratifying to discover that the *aphides*, which at that time threatened the trees with destruction, have almost disappeared. Whether this result is owing to the increase of other insects—their enemies, or to some other cause, I have not been able to discover.

The curculio, I think will not do us much damage. From the havoc which we made amongst them last year, when we destroyed almost thirteen hundred in my fruit garden, they have not yet recovered; and I feel encouraged, that with a little attention properly directed, these colonists will no longer be formidable.

Into your valuable paper of last year, an account of our method of taking the curculio was copied, in which I showed the advantage of a *smart stroke* in detaching them from the trees. To strike against the side of a tree, or limb,—bruises it; and it is, therefore, necessary to provide a *striking place*. This spring, I sawed off one or more lateral branches of about an inch in diameter from each tree, leaving a stump to project, from which I removed the bark that the wood might *harden*; and also, made the head convex with a knife, to prevent it from *battering* under the mallet. It is important that these stumps project nearly at right angles from the tree; otherwise the effect of the blow will be lessened.

On some trees, however, there are no limbs to spare, or none that project in a good direction. In those cases, something more *artificial* must be provided. A *turned* pin of *hard* wood, with a shoulder, may be inserted; and if painted, it would continue for years. The harder the wood, the better; for the more violent the jar, the greater is the certainty of bringing them down from the tree. D. T.

TO DESTROY CATERPILLARS.—A piece of woollen rag had been blown by the wind into a entrant bush, and when taken out was found covered by these leaf devouring insects. Pieces of woollen cloth were immediately placed on every bush in the garden, and the next day the caterpillars had universally taken to them for shelter, and were then easily destroyed.

* American Farmer, vol. 14, p. 125.

(From the Genesee Farmer.)

FINE FRUIT.

The letter from which we take the following extract, was received more than two months since and mislaid, or we should sooner have given it a place in our pages. It is from a subscriber in Hudson. If it shall induce but one farmer to plant a grapevine, we shall think the space it occupies well filled.

"An increasing attention is paid in this country, as elsewhere through the state, to agriculture; but a practical *action*, I wish I could say *attention*, is increasing here in a still greater degree in horticulture. In this, however, little more is yet done here, than to receive the rays of light which stray from other more luminous points, and to direct them as well as we can into gardens and orchards.

"The real difference between first rate fruit of any species, and the common kinds, is understood by few; and by fewer still, is the difference understood between allowing such fruits to grow, as spring spontaneously around them, and by skill and attention *begetting* upon dame nature in her old age, a new, more lovely, and charming progeny, and training them to possess and exhibit more beautiful and excellent qualities, and to exercise a more benign and pervading influence, than any of her elder born. A diffusion of more of the *elements* of horticulture, is what most of us need.

"The error in most papers of the kind, and I think of yours, is, that it gives its readers credit for more knowledge in the first principles of the art than they possess, or think they possess; and as they are uniformly too modest to avow their ignorance, they continue unenlightened, and struggle daily with difficulties, without practice, without tuition which is radical, and without leisure for that constant observation which alone can compensate for a want of primary instruction. I speak from experience. I was bred to practical agriculture, as it was understood at and around the house of my childhood and youth. But horticulture, in its elements, and in its choice and elegant departments, was all a mystery to me. And so it was with others, and is so yet to nearly the same extent. My farm now, is less than an acre. The choicest things which can be grown to regale the senses and awaken devotional feelings, are those and those only, which seem worthy to occupy my leisure hours, adorn the play grounds, and look on the pastimes of my children. I have not time to spell out from the book of nature, the lessons I am anxious to learn; I do not know on what page of that glorious book I may find them, even to spell at. The gardens, and the rich fruits of the experienced, are out of the range of my vocation. What I occasionally see of them, seems like glimpses of enchanted ground, and I sigh in vain for their possession; for like most others, I am chained down to duties which lead me perforce away.

"Where then, but from the press, and in the periodical page, am I, and those like me, to find the information I need? Four years ago I began my little plantation. I thought, among other things, to construct a large harbor, and have it covered with vines, that my infant brood, in the open air, might be sheltered from the burning suns of summer. I then thought the wild grape of my native woods, for hardihood and foliage, the best for my purpose. Opportunely a number of the New York Farmer met my eye, in which I first learnt of the Isabella, red Bland, and others, hardy as those which clothed the hills I rambled over in boyhood, and far exceeding them in luxuriance of foliage and excellence of fruit. Immediately I sent my subscription for the paper, and my order for the plants I wished, and for two years past, myself and household have literally enjoyed, and "sat under our own vines," and gathered from them in abundance the fruit of our labor. I now have vines of almost incredible growth of eight varieties of hardy grapes of great excellence, besides foreign varie-

ties; most of which have borne much fruit for two years, and interlacing their long branches far above our heads, they reached toward us as if in mockery, their rich clusters of different colors, side by side.

"In the fruiting season, it is a rich feast to the eye and to the heart, not of children only, but also of any one, who can look through these good things of a gracious Providence, to the great Giver of all! But though most of my neighbors suppose me before them in horticulture, and in a single branch of it I may be, yet in all things else I am like them in ignorance of its principles, and of nearly every thing useful to the unpractised. We want to be taught its alphabet—its simplest combinations—its first operations—its plainest processes; the very things which the adept supposes the child must know. Of these we are all, nearly all of your subscribers deplorably ignorant; and too proud to ask. Those who contribute to your work, seem desirous to show their science,—their rare discoveries. All this is well; but it is not well that this should be all. The season is at hand, when 'line upon line and precept upon precept,' of the most familiar things to the initiated, will be like grains of gold to ninety-nine hundredths of your readers. I wish I could deposit such precious seed, that it might weekly fly, on thousand, thousand wings, and bear abroad from your press, embryo, wealth and happiness to all the land. But though I cannot, there are those who can, and I hope the season as it opens will teem with it."

(From the London Horticultural Register.)

STRIPED HOUSAINEE MELON.

This melon is, to the present day, scarcely known in this country; in fact, it was not at all known, until Mr. Knight gave a description of it in the Horticultural Transactions, of 1831.

The striped Housainee melon is a noble fruit, one of great beauty and excellence; its skin is firm, but thin; the rind under it, and the fleshy cellular substance adjoining, to the depth of rather more than the eighth of an inch, is of a bright green, gradually becoming paler, till it meets and blends with a bulk of the flesh, which is of a pinkish buff, or salmon color; the green portion is not quite so tender and juicy as the internal substance; but the whole may be eaten so as to have nothing remaining, but the thin exterior integument; there is no fraud in this fine fruit, all is juicy and eatable, the flavor is delicious, the odor that of a fragrant apple, and the fruit will long remain good without decay.

In its form this melon resembles an egg, the stalk end being more enlarged than that of the blossom. It is, during its early growth, of a dark green color, but, as its age advances, the stripes become very apparent; they are of a full sombre green, and divide the surface into distinct marked portions, leaving it, however, perfectly free from grooves or furrows; and hence this variety may be styled a *smooth melon*, although it finally becomes reticulated with an ash-grey colored net work. When near to maturity, small greenish yellow spots are manifest among the interstices of the netting, and a clear yellow circle surrounds the part at the insertion of the footstalk. There is no determinate change of color, that absolutely marks the state of perfect maturity, at least I have not perceived such; the general tint appears to me to be a glaucous or sea-green, covered more or less with a pale greyish tissue of vermicular reticulations. In some individuals, the green stripes remain very conspicuous to the last; in others, they become almost obliterated.

The plant, in its habit of growth, is one of the finest and most interesting objects imaginable. The stem, if led perpendicularly up to the height of three feet, will comprise about ten clear joints. From each joint, at its angle, a noble leaf nearly a foot in diameter is produced; it is supported by a *petiole* (footstalk) about ten inches in length, that takes a most

graceful double bend, in figure resembling the branch of a chandelier. The plate of the leaf is of a most vivid green, its surface rough, with short bristly hairs. In shape it is obtusely heart-shaped, and very broad near the base. From the axles of these leaves, lateral shoots would naturally be sent forth, but each of these is to be removed to a certain height, for a reason that will in due time be assigned.

The flowers both male and female are small, frequently not exceeding three-fourths of an inch in diameter, at the extreme edges of the *limbus* or border, they are of a sulphur or pale yellow color, rather few in number. The males, as far as my observation extends, are produced somewhat before the fertile blossoms, and this appears to be a wise provision of nature, to insure the safety and perfection of the fruit; the melons formed above the tenth joint are generally found to set with greater certainty, and to grow to a greater size than others that appear during the infantile state of the plant, nearer to its roots.

"The Housainee melon," as Mr. Knight justly observes, is upon the whole "of very easy culture," and the plant very productive of fruit; but "that it is very long in ripening." When ripe, however, he adds, "it remains in perfection, a very valuable quality to the grower." Another feature, and one that he deems of great moment, is, that "the natural habits of the plant, which he feared would not prove permanent, he has founded to be strictly so." I have quoted his own words to me, merely changing the person, and I may add, that the only circumstance worthy of real regret is, that the fruit is not only tardy, but somewhat irregular in the period of its ripening.

(From the Tioga Phenix.)

GIRDLING PEAR TREES.

MR. SMITH:

June 26, 1833.

Many of your readers may perhaps recollect your notice of the effect of girdling on two pear trees in my garden—the following communication from Dr. Mease, of Philadelphia, is at your service, and will doubtless be interesting to your patrons. It may be well to state that these trees were destroying (by shading and sending their roots and numerous sprouts into) a fine bed of asparagus, and not having borne any fruit, I took this method to destroy what I deemed useless and barren trees, and thereby preserve a productive and valuable part of my garden.

The trees were girdled in August, 1830, the next year both carried an unusual quantity of excellent fruit—in 1832, we had the promise of an equally abundant crop, but it was all destroyed by severe and late frosts; at the present time, one of the trees has a fine quantity of fruit, but it begins to fall rapidly, and I am inclined to believe that but few, if any, will ripen.

The leaves of the trees are uncommonly small, few in number, and presenting somewhat the appearance of having been stripped of their foliage by the caterpillar; the general appearance of both the trees is now far from flourishing, and I expect they will hardly survive another winter.

S. W. M.

Philadelphia, June 12, 1833.

JUDGE MORRIS, Wellsborough:

Sir,—About this time last year I read a statement which originally appeared in the *Tioga Phenix*, of your two pear trees having been made to bear fruit by the operation of girdling, which had been performed for the purpose of killing them, in consequence of your supposing them barren; they not having borne except slightly on two occasions. The article was headed "*Natural Curiosity*," and from the editor's remark, it would seem, that the fact was new to him. As he called for an explanation of it, and none has been furnished, I offer you one.

Although the girdling of a tree or branch to cause them to bear, may be deemed strange, it has long been familiar to those who have attended to the culti-

vation of fruit trees, and has often been done with the express view of causing seedling trees to produce prematurely, that the quality of their fruit might be tested, and in reference to their future propagation. In the first Philadelphia edition of Dr. Willich's *Domestic Encyclopedia*, article "fruit," I mentioned the process in an extract from Dr. Darwin's delightful work "*Phytologia, or the Philosophy of Agriculture and Gardening*," a work by the way which every library, and every country gentleman in particular, ought to possess, after the edition of the Bible, prepared according to the recommendation of the Rev. Dr. Watts. Considering that my edition of Dr. Willich's work was published so long since as the year 1803, that 1000 copies of it were sold, and that 1000 copies of a more recent edition by Professor Cooper were printed, it is singular that the fact in question should not have been known to some one in Tioga county, and that the theory or explanation of it has not been given. The unexpected fertility of your trees was owing to the unusual accumulation of "*proper juice*," or *cambium* in the leaves and branches, in consequence of the interruption of its downward progress by the girdling. These names are given by phytologists, to the sap when duly elaborated by the processes of vegetation, but into the consideration of which I cannot now enter. It may be enough to say, that it constitutes the grand principle of vegetable organization, generating and developing in succession the several organs of the plant, or furnishing the vital principle with the immediate materials of assimilation, and which, as proved by the experiment of Dr. Darwin, are conveyed by a set of branching vessels, originating in the extremities of the leaves, on each side of the mid rib, and ascending with it into the leafstalk, whence it is carried by the longitudinal vessels of the inner bark down to the extremities of the roots. This *cambium*, if it does not form the buds, most certainly nourishes them and causes their development. This is the true philosophy of what took place in your pear trees, and thus is the apparent mystery of the effect of girdling them, solved. I have myself tried the experiment of ringing two barren branches of a plum tree with great success. Old trees which had ceased to bear have again been rendered productive by ringing. I recollect that several years since an English periodical recorded such a case, as having occurred in the garden of Lord Drummond, in Scotland. The same effect has been observed to take place by twisting a wire or cord round a branch (which had never borne) so tight as to form a considerable protuberance above the ligation. Several years since I was told of a young fruit tree having been forced to bear, by having one end of a clothes line fastened to it in the spring, and suffered to remain for some months until the enlargement became obvious. Another mode of effecting the accumulation of the *cambium*, is to slip the neck of a porter bottle, or a hollow bone, down the limb to near its junction with the body of the tree, and to leave it there, until the branch fills the cavity, when from the obstruction to the descending juice, a circular ring of bark will form above the tube. This I saw practised by the late A. C. Du Plan, thirty years since on the Schuylkill. I am induced to believe this practice originated in France. Another mode of forcing a branch to bear, is to bend it nearly or entirely to the ground, and fixing it there by pegs, or by applying a heavy ball of clay to its extremity. The "*proper juice*" being thus diverted from its natural course, the formation of leaf buds will be retarded, and that of fruit buds promoted, even down to the lowest spur on the stem and thickest branches. The ringing of trees must be done with caution, otherwise the privation of nourishment in the roots will cause the death of the tree. The rule is to confine the operation to over luxuriant shoots of one or two years' growth, and to proportion the dimensions of the ring to the degree of softness which the roots can undergo, without material injury; or not to make the ring wider than can

be healed during the following season; the ring also should be covered to defend its edges from the weather. I wish to know whether the girdling of your pear trees has injured their health. The limbs which I ringed were cut off the year after, owing to their great length proving inconvenient where the tree grew, and I was thus unable to ascertain if they would have suffered from the operation performed on them. I am, very respectfully,

JAMES MASE.

Prices Current in New York, July 13.

TALL MEADOW OAT GRASS SEED.

I shall have by about the 15th of August next 200 bushels of Tall Meadow Oat Grass Seed, for sale at this Establishment. The price will be ascertained and advertised when the seed comes to hand. It is of this year's growth, and will doubtless be good, as it is saved by the same farmer who has supplied me heretofore.

I. I. HITCHCOCK,
American Farmer Establishment.

BAKEWELL SHEEP.

The Subscriber has become agent for John Barney, Esq. for the sale of his celebrated Bakewell Sheep. The stock now on hand for sale, is the following: Eight or ten EWES, of good age and quality, at prices from \$10 to \$50.

About the first of September next, I shall have from the same flock six or eight Rams of this year's stock. Price \$50 each.

I shall have about the same time, from the flock of another celebrated breeder, a few Ram lambs—half Bakewell and half Southdown. Prices from \$30 to \$40 each. Address.

I. I. HITCHCOCK,
American Farmer Establishment.

DEVON CATTLE.

For sale by the Subscriber, one Devon Bull, ten months old; a handsome and promising calf. Price \$100. Also, a very beautiful and valuable Devon Heifer, two years old. Price \$175.

I. I. HITCHCOCK,
American Farmer Establishment.

TURNIP SEED.

For sale the following kinds of Turnip Seed, of the very first quality, at 75 cts. per pound.

EARLY WHITE DUTCH.

GARDEN STONE.

WHITE FLAT. GREEN ROUND.

RED ROUND OR RED TOP.

WHITE NORFOLK. WHITE TANKARD.

YELLOW ABERDEEN. RUTA BAGA.

And, as usual, a complete assortment of GARDEN SEEDS generally.

I. I. HITCHCOCK,
American Farmer Establishment.

TURNIP AND MILLET SEEDS.

J. S. EASTMAN has in store prime fresh large White, Flat, and Red Top Turnip Seed, and fresh Millet Seed. Also seed Buckwheat, together with a general assortment of Garden Seeds and Harvest Tools, and Agricultural Implements generally. Also Fox & Borland's Patent Threshing Machines, with spring concaves.

July 12.

DURHAM SHORTHORN CATTLE.

I have for sale the following fine animals:

One full blood Bull, nineteen months old, by Gloster, out of a first rate full bred cow. He is not above middling size, but is a very beautiful and perfect animal. Price \$250.

One full blood bull, two years old—a very fine animal. Price \$50.

One full bred Heifer, two years old, now springing, but the calf will not be valuable, being (accidentally) by a common bull. She is a very fine Heifer, and will be sold for \$225.

Less than Full Blood.

One Bull, three years old, fifteen-sixteenths Durham; has been pronounced by good judges as fine an animal as was ever in the United States. He would be worth twice the price now asked for him if he had the other sixteenth of Durham blood. He will be sold for \$500.

One Bull, fifteen months old, from good stock, seven-eighths Durham. Price \$225.

One Bull, three years old, half blood Durham, a very handsome animal, and from good stock. Price \$150.

One Cow, eight years old, seven-eighths Durham, a fine breeder, and now in calf by a full blood bull. Price \$100.

Three Milch Cows, half blood Durham, very good milkers, and of good size and form; calves from two to six weeks old. They will be sold for \$50 each.

Address
I. I. HITCHCOCK,
Amer. Far. Establishment.

TURNIP SEED, BUCKWHEAT, &c.

400 lbs. White Flat and Red Top Turnip Seed.
100 lbs. Ruta Baga or Swedish do do

The above is of the present year's growth and raised under the immediate superintendence of Robert Sinclair, whose long success in raising this article warrants us in recommending it with the greatest confidence.

Also, Early White Dutch Tankard.

Yellow Bullock and Yellow Stone Turnip.

200 lbs. Fall Radish Seed, consisting of White and Black Spanish, Long White Summer, &c.

100 lbs. prime London Early York Cabbage Seed, Early George, Green Savoy, Flat Dutch, and many other kinds suitable for Fall Sowing.

IN STORE:

50 bushels Seed Buckwheat.

100 bushels Herds grass.

50 bushels Tall Meadow Oat Grass.

200 lbs. Canary Seed.

1500 lbs. Yellow Lentil Seed.

150 lbs. Yellow Mustard Seed.

WANTED.—Clover, Timothy and Orchard Grass Seed, for which the highest price will be given.

July 13.

SINCLAIR & MOORE.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street.

Ap. 26.

WANTED,

All kinds of GRASS SEED, for which a fair price will be given, by
I. I. HITCHCOCK,
American Farmer Establishment.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—Considerable improvement will be noticed in the prices of flour and wheat. Howard street flour, fresh ground, from wagons, is selling at \$5 57½. The price of City mill's flour is enhanced considerably by the mixture of new with old wheat, and by its freshness. Our quotations apply to new wheat exclusively. In other articles no variation.

THE FARMER.

BALTIMORE, FRIDAY, JULY 26, 1833.

MILCH COWS.—We are frequently asked what breed of cattle we think best for the dairy, and as we have taken no inconsiderable pains to inform ourselves on this subject, both by actual observation and obtaining the opinions of a great number of practical men, we think proper to answer the question in this way. Were we about commencing a dairy, our choice would be, without hesitation, half blood Durham Shorthorns. We should be particular in selecting those by a first rate Durham Shorthorn bull, out of some of our best common cows, and if we could procure them from the hornless or buffalo breed, so much the better. Half blood Shorthorns are almost always good milkers, and first rate butter makers, averaging, in good pasture, eight to ten pounds of butter per week. We have to support us in this opinion, the testimony of several practical and intelligent persons, who have had both full blood and half blood cow; and among these persons is a lady in Pennsylvania, whose husband owns some of the finest Durham Shorthorn stock in America. This lady superintends her dairy herself, and has witnessed the milking of the full and half blood cows for many years; she has kept their milk and cream separate, and ascertained the quantities of milk and butter yielded by both; and has thus been able to decide with scarcely the possibility of error. Her trial of both breeds has not been confined to one or two select animals—she generally has half a dozen of each, and as her husband deals largely in this kind of stock, her cows are continually changing. She also has Devon cows, and half blood cows of the same; but her preference for the dairy, is as stated above, decidedly in favor of half blood Durhams. It is true her cows run in good pasture, without which no breed can be good milkers. Where the pasture is short, without doubt, the North Devons are the best, because they do keep in good condition in pasture that Durhams would fail in.

But a word to those who wish to obtain deep milkers. Whoever would have a large quantity of milk, and that of good quality, must provide good pasture and good water. You might as well expect a good crop of corn, from a sand hill without manure and rain, as a large quantity of milk from a cow in poor pasture with bad water. And, let us remark, good water is as essential to good milk yielding as good pasture. We had a cow last summer that yielded five gallons of rich milk a day. She ran in a tolerable pasture, but there was a stream of pure spring water running through it. We also kept salt constantly within her reach. The same cow this summer, in a much better pasture, does not yield three gallons of milk. The reason of this falling off, is, that she is supplied with water from a pump, occasionally, when her attendants conceive she wants it—not when she thinks she wants it, which is the great point. She also gets salt “as it happens.”

We have often heard of cows giving large quantities of milk, that “eat scarcely any thing,” to which we always reply—“tell that to the marines, for old sailors won’t believe you.” A cow cannot make milk out of nothing; and she can only give you milk in proportion to the quantity of good food you give her.

In giving our opinion of the best milkers, we know we render ourselves obnoxious to the criticism of those who own other breeds. There are three or four parties to this question, which may be named after the breeds of animals they prefer. They are full blood Durham shorthorns, half blood Durham shorthorns, North Devons, Alderneys, &c. The party to which we belong is indicated above.

DISSEMINATION OF TREES AND PLANTS.—The scientific and zealous American Consul at Campeachy, has just laid his countrymen and fellow citizens under

renewed obligation, by transmitting the seeds of some rare, important, and most remarkable trees, on whose properties it is useless for us to comment, as he describes them himself; and he “who runs may read.” Perhaps (but it is only conjecture) the last in order, the habi tree, has the best chance of being successfully propagated in our climate; for the huge corozo seems essentially tropical. But let us try all experiments, and some will succeed.

We are highly gratified to hear that the *Agave* America, (great Aloe,) sent by the same indefatigable gentleman, to Mr. Gordon, is planted and flourishing in the grounds belonging to the Charity Hospital. It is the only one of the species in the United States. How the sisal or diablitos, (stingless bees, literally “little devils,”) conveyed hither at the same time by Mr. PERRINE, have been disposed of, we are curious to learn. The sisal would most probably grow any where in our more southern states, and furnish cordage, &c. of uncommon tenacity and durability.

Not long since the papers informed us of an edible root being imported from Peru or Chili, more nutritive than the potato. Is it the famous *Oca*, or is it the South American *Ipis*?

Should none of these exotics be susceptible of naturalization in our soil and climate, which we are reluctant in believing, our Consul would still merit a vote of thanks from all our botanists, planters, gardeners, and statesmen, for tanning our zeal by his ardor.—*New Orleans Bulletin*.

Consulate U. S. A. Campeachy, June 15, 1833.

Sir,—I send you in the schooner *Francisca*, a bag containing the fruits of three kinds of trees, which have here the names of pich, corozo, and habi. The fruit of the pich, so singular in shape, is obtained from a beautiful shade tree, whose branches extend four to five hundred feet in circumference, which is larger than the *Adansonia digitata*, or great Boabab, hitherto asserted to be the largest or rather broadest tree in the world.” In the plantations of this Peninsula, it is a natural shed for cattle, and in the villages it is a hospitable roof for travellers, to shelter great numbers from the burning rays of a tropical sun.

The nuts called corozo grow in clusters as large as barrels, on a stout but handsome palm tree of *Tabasco*, which I believe to be the *Alfonisa oleifera* of botanists, or the American oil-bearing palm.

The four winged seeds called habi, are taken from the Leguminous trees of that name, (*Piscidia erythrina*.) whose timber is as highly prized for ship building in Yucatan, as the live oak of the United States, or the teak in the East Indies, and is therefore equally entitled to the care of our national government in its plantation at Pensacola.

All Campeachy built vessels have their timbers of *habi*, and their planks and upper works of the *cedro* of this district, and notwithstanding the enormous cost of ship building here, they are preferred on account of their great durability to the best American merchant vessels at half their price. Both are ornamental trees, which if once planted at the southern extremity of East Florida, will gradually extend up that Peninsula, and become very valuable additions to the resources of our navy.

I have the honor to be, sir, very respectfully, your obedient servant,

HENRY PERRINE.

THE LOVE OF THE UNSEASONABLE.—The absurdities of this exceedingly civilized land yield an abundant harvest to the observer; a man with a taste for them, with but a small annuity to supply his necessities, might live a most luxurious life on the follies of the capital alone. What necessity for plays or operas, or parties or races, which the ways of London open to him? But then he must have a true relish for them; he must be no cynic to sneer, but an epicure in folly, who hugs himself and chuckles with delight over a nice little piece of true absurdity. The prevalent “love of the unseasonable” is a fine exam-

ple of folly. The sight of people buying green peas in April, at four guineas a quart, and raspberries at half a crown an ounce, would be a treat for a whole evening to one who revelled in such entertainment. Bad peas in April, at a price as dear as gold, instead of fine peas in June, at the price of bread or potatoes, and that not from any eager longing, or any excessive love of the pea-flavor, but simply that people may open their eyes at table, and exclaim in their hearts, “what an amphitryon!” If chips were to be had only at the same price, they would be presented in a consommé of bank notes. A man who has green peas at his table in April, knows that thereby he is one of few; he is an exclusive *par force*, or forcing. To enjoy the same pleasure that many share, is alien to the spirit of England, and this is the principle and secret of the race of fashion in this country. The few enjoy a pleasure till the many gradually learn its source and master its approaches; it is then deserted for another. Rank and riches are forever “seeking pastures new;” when the vulgar herd rushes in, away they troop like sacred fowl. Society in England is constructed on the same principle attributed to matter, which is held together by the attraction of cohesion, and held off from a too close union by the attraction of repulsion. We are bound together in one whole of civilization, but detest fellowship; separate ourselves into small divisions, and when these divisions cannot be kept up naturally, we do it artificially; and when other means fail, resort to green peas in April. [*English Journal*].

DOMESTIC SILK.—We are glad to perceive that several persons in this section of country are turning their attention to the culture of silk—an occupation amusing and profitable, while it is not at all laborious. Some weeks ago we saw a beautiful specimen of sewing silk, manufactured in the family of Capt. Lewis Brown, of this place; and on Tuesday morning last, a gentleman called at our office and exhibited a quantity of the same article, manufactured by the lady of Mr. Robert Mills, of Bedford county. Raising silkworms and the culture of silk is attended with so little trouble and expense, that we hope it will be generally practised by the ladies, who will find it no inconsiderable source of revenue.—*Lynchburg Virg.*

FOREIGN MARKETS.

LIVERPOOL COTTON MARKET.

June 8.—We have had a spirited demand for cotton throughout the week, and a general improvement in prices of full 3-8 per lb., at which advance market closes steadily. The import this week is 31,838 bags, and the sales reach 47,270 bags, viz: 890 Sea Islands, 12½d to 23d; 90 stained do. 8d to 11d; 23,500 Boweds, 6 7 8d to 8 3-8d; 15,360 New Orleans, 7d to 9½d; 3,950 Alabama, 7 to 8½d; 3,869 Pernams, 9 to 10½d; 1,070 Bahias 8 5 8d to 9½d; 3,546 Maranhams, 8½d to 10d; 150 Para, 8½d; 90 Demararas, 9½d to 10½d; 10 Bardoos; 12d; 230 common West Indies, 6 3-8d to 8½d; 50 Smyrnas, 7d to 7½d; 170 Egyptians, 10d; and 4,810 Surats, 5 to 6½d per lb.

Extract of a Letter.—We have had a very animated demand for cotton during the week, attended with an advance to an extent rather unexpected, (say 3 8d on common quality.) The accounts from the U. S. respecting the probable deficiency in their crop, together with the general approval by the public, of the ministerial plan for renewing the charter of the Bank of England, have had an effect in giving increased confidence in cotton, while the low state of the stocks in the interior compelled the trade to come forward for large supplies. Trade in the interior gives promise of improvement; but thus far, although there is some advance on yarns, the advance on goods is rather asked than obtained. Of the sales of the week about 15,000 bales are supposed to be on speculation, (including 11,000 American) and nearly 200 for export, leaving about 30,000 for consumption.

AGRICULTURE.

(From the Farmers' Register.)

SUPPLEMENTARY CHAPTER TO

"AN ESSAY ON CALCAREOUS MANURES."

The use of calcareous earth recommended to preserve putrescent manures, and to promote cleanliness and health.

The operation of calcareous earth in enriching barren soils, has been traced, in a former part of this Essay, to the chemical power possessed by that earth of combining with putrescent matters, or with the products of their fermentation—and in that manner, preserving them from waste, for the use of the soil, and for the food of growing plants. That power was exemplified by the details of an experiment, (page 91,) in which the carcass of an animal was so acted on, and its enriching properties secured. That trial of the putrefaction of animal matter in contact with calcareous earth, was commenced with a view to results very different from those which were obtained. Darwin says that *nitrous acid* is produced in the process of fermentation, and he supposes the *nitrate of lime* to be very serviceable to vegetation.* As the nitrous acid is a gas, it must pass off into the air, under ordinary circumstances, as fast as it is formed, and be entirely lost. But as it is strongly attracted by lime, it was supposed that a cover of calcareous earth would arrest it, and form a new combination, which, if not precisely nitrate of lime, would at least be composed of the same elements, though in different proportions. To ascertain whether any such combination had taken place, when the manure was used, a handful of the marl was taken, which had been in immediate contact with the carcass, and thrown into a glass of hot water. After remaining half an hour, the fluid was poured off, filtered, and evaporated, and left a considerable proportion of a white soluble salt, (supposed eight or ten grains.) I could not ascertain its kind—but it was not deliquescent, and therefore could not have been the nitrate of lime. The spot on which the carcass lay, was so strongly impregnated by this salt, that it remained bare of vegetation for several years.

But whatever were the products of fermentation saved by this experiment, the absence of all offensive effluvia throughout the process sufficiently proved that little or nothing was lost—as every atom must be, when flesh putrefies in the open air: and I presume that a cover of equal thickness, of clay, or sand, or of any mixture of both, without calcareous earth, would have had very little effect in arresting and retaining the æriform products of putrefaction. All the circumstances of this experiment, and particularly the good effect exhibited by the manure when put to use, prove the propriety of extending a similar practice.—In the neighborhood of towns, or wherever else the carcasses of animals, or any other animal substances subject to rapid and wasteful fermentation, can be obtained in great quantity, all their enriching powers might be secured, by depositing them between layers of marl, or calcareous earth in any other form. On the borders of the Chowan, immense quantities of herrings are often used as manure, when purchasers cannot take off the myriads supplied by the seines.—A herring is buried under each corn hill, and fine crops are thus made as far as this singular mode of manuring is extended. But whatever benefits may have been thus derived, the sense of smelling, as well as the known chemical products of the process of putrefaction, make it certain that nine-tenths of all this rich manure, when so applied must be wasted in the air. If those who fortunately possess this supply of animal manure, would cause the fermentation to take place and be completed, mixed with and enclosed by

marl, in pits of suitable size, they would increase prodigiously both the amount and permanency of their acting animal manure, besides obtaining the benefit of the calcareous earth mixed with it.

But without regarding such uncommon, or abundant sources for supplying animal matter, every farmer may considerably increase his stock of putrescent manure, by using the preservative power of marl; and all the substances that might be so saved, are not only now lost to the land, but serve to contaminate the air while putrefying, and perhaps to engender diseases. The last consideration is of most importance to towns, though worthy of attention every where.—Whoever will make the trial will be surprised to find how much putrescent matter may be collected from the dwelling house, kitchen, and laundry of a family; and which if accumulated (without any calcareous earth) will soon become so offensive as to prove the necessity of putting an end to the practice. Yet it must be admitted that when all such matters are scattered about (as is usual both in town and country,) over an extended surface, the same putrefaction must ensue, and the same noxious effluvia be evolved, though not enough concentrated to be very offensive, or even always perceptible. The same amount is inhaled, but in a very diluted state, and in small, though incessantly repeated doses. But if mild calcareous earth in any form (and fossil shells present much the cheapest) is used to cover and mix with the putrescent matters so collected, they will be prevented from discharging offensive effluvia, and preserved to enrich the soil. A malignant and ever acting enemy will be converted to a friend and benefactor.

The usual dispersion and waste of such putrescent and excrementitious matters about a farm house, though a considerable loss to agriculture, may take place without being very offensive to the senses, or injurious to health. But the case is widely different in towns. There, unless great care is continually used to remove or destroy filth of every kind, it soon becomes offensive, if not pestilential. During the last summer, when that most horrible scourge of the human race, the Asiatic cholera, was desolating some of the towns of the United States, and all expected to be visited by its fatal ravages, great and unusual exertions were every where used to remove and prevent the accumulation of filth, which, if allowed to remain, it was supposed would invite the approach, and aid the effects of the pestilence. The efforts made for that purpose served to show what a vast amount of putrescent matter existed in every town, and which was so rapidly reproduced, that its complete riddance was impossible. Immense quantities of the richest manures, or materials for them, were washed away into the rivers—caustic lime was used to destroy them—and the chloride of lime to decompose the offensive products of their fermentation, when that had already occurred. All this amount of labor and expense was directed to the complete destruction of what might have given fertility to many adjacent fields, and yet served to cleanse the towns but imperfectly, and for a very short time. Yet the object in view might have been better attained by the previous adoption of the proper means for preserving these putrescent matters instead of destroying them. These means would be to mix or cover all accumulations of such matters with rich marl, (which would be the better for the purpose if its shells were in small particles,) and in such quantity as the effect would show to be sufficient. But much the greater part of the filth of a town is not, and cannot be accumulated; and from being dispersed, is the most difficult to remove, and is probably the most noxious in its usual course of fermentation. This would be guarded against by covering thickly with marl, the floor of every cellar and stable, back yard and stable lot. Every other vacant space should be lightly covered. The same course pursued on the gardens and other cultivated grounds, would be sufficiently compensated by the increased product that would be obtained; but independent of

that consideration, the manures there applied would be prevented from escaping into the air—and being wholly retained by the soil, much smaller applications would serve. The streets ought also to be sprinkled with marl, and as often as circumstances might require. The various putrescent matters usually left in the streets of a town, alone serve to make the mud scraped from them a valuable manure; for the principal part of the bulk of street mud is composed merely of the barren clay, brought in upon the wheels of wagons from the country. Such a cover of calcareous earth would be the most effectual absorbent and preserver of putrescent matter, as well as the cheapest mode of keeping a town always clean. There would be less noxious or offensive effluvia, than is generated in spite of all the ordinary means of prevention; and by scraping up and removing the marl after it had combined with and secured enough of putrescent matter, a compost would be obtained for the use of the surrounding country, so rich and so abundant, that its use would repay a large part, if not the whole of the expense incurred in its production. Probably one covering of marl for each year would serve for most yards, &c. but if required oftener, it would only prove the necessity for the operation, and show the greater value in the results. The compost that might be obtained from spaces equal to five hundred acres in a populous town, would durably enrich thrice as many acres of the adjacent country: and after twenty years of such a course, the surrounding farms might be capable of returning to the town a ten-fold increased surplus product. After the qualities and value of the manure so formed were properly estimated, it would be used for farms that would be out of the reach of all other calcareous manures. Carts bringing country produce to market might with profit carry back loads of this compost six or eight miles. The annual supply that the country might be furnished with, would produce very different effects from the putrescent and fleeting manure now obtained from the town stables. Of the little durable benefit heretofore derived from such means, the appearance of the country offers sufficient testimony. At three miles distance from some of the principal towns in Virginia, more than half the cultivated land is too poor to yield any farming profit.—The surplus grain sent to market is very inconsiderable—and the coarse hay from the wet meadows can only be sold to those who feed horses belonging to other persons.

But even if the waste and destruction of manure in towns was counted as nothing, and the preservation of health by keeping the air pure was the only object sought, still calcareous earth, as presented by rich marl, would serve the purpose far better than quick lime. It is true, that the latter substance acts powerfully in decomposing putrescent animal matter, and destroys its texture and qualities so completely, that the operation is commonly and expressively called "burning" the substances acted on. But to use a sufficient quantity of quick lime to meet and decompose all putrescent animal matters in a town, would be intolerably expensive and still more objectionable in other respects. If a cover of dry quick lime in powder was spread over all the surfaces requiring it for this purpose, the town would be unfit to live in; and the nuisance would be scarcely less, when rain had changed the suffocating dust to an adhesive mortar.—Woolen clothing, carpets, and even living flesh would be continually sustaining injury from the contact. No such objections would attend the use of mild calcareous earth: and this could be obtained probably for less than one-fifth of the cost of quick lime, supposing an equal quantity of pure calcareous matter to be obtained in each case. At this time the richest marl on James river may be obtained at merely the cost of digging, and its carriage by water, which if undertaken on a large scale, could not exceed, and probably would not equal three cents the bushel.

The putrescent animal matters that would be preserved and rendered innocuous by the general marling

*Darwin's Phytologia, pp. 210 and 224. Dublin Edition.

of the site of a town, would be mostly such as are so dispersed and imperceptible that they would otherwise be entirely lost. But all such as are usually saved in part, would be doubled in quantity and value, and deprived of their offensive and noxious qualities by being kept mixed with calcareous earth. The importance of this plan being adopted with the products of privies, &c. is still greater in town than country. The various matters so collected and combined should never be applied to the soil alone, as the salt derived from the kitchen, and the potash and soap from the laundry, might be injurious in so concentrated a form. When the pit for receiving this compound is emptied, the contents should be spread over other and weaker manure, before being applied to the field.

Towns might furnish many other kinds of rich manure, which are now lost entirely. Some of these particularly require the aid of calcareous earth to be secured from destruction by putrefaction, and others, though not putrescent, are equally wasted. The blood of slaughtered animals, and the waste and rejected articles of wool, hair, feathers, skin, horn and bones, all are manures of great richness. We not only give the flesh of dead animals to infect the air, instead of using it to fertilize the land, but their bones which might be so easily saved, are as completely thrown away. Bones are composed of phosphate of lime, and gelatinous animal matter, and when crushed, form one of the richest and most convenient manures in the world. They are shipped in quantities from the continent of Europe to be sold for manure in England. The fields of battle have been gleaned, and their shallow graves emptied for this purpose; and the bones of the ten thousand British heroes who fell on the field of Waterloo, are now performing the less glorious, but more useful purpose of producing wheat for their brothers at home.

There prevails a vulgar but useful superstition, that there is "bad luck" in throwing into the fire any thing, however small may be its amount or value, that can serve for the food of any living animal. It is a pity that the same belief does not extend to every thing that, as manure, can serve to feed growing plants—and that even the parings of nails, and clippings of beard are not used (as in China) in aid of this object. However small each particular source might be, the amount of all the manures that might be saved, and which are now wasted, would add incalculably to the usual means for fertilization. Human excrement, which is scarcely used at all in this country, is stated to be even richer than that of birds; and if all the enriching matters were preserved that are derived not only from the food, but from all the habits of man, there can be no question but that a town of ten thousand inhabitants, from those sources alone, might enrich more land than could be done from as many cattle.

The opinions here presented are principally founded on the theory of the operation of calcareous manures, as maintained in the foregoing part of this Essay; but they are also sustained to considerable extent by facts and experience. The most undeniable practical proof of one of my positions, is the power of a cover of marl to prevent the escape of all offensive effluvia from the most putrescent animal matters. Of this power I have made continued use for about eighteen months, and I know it to be more effectual than quick lime, even if the destructive action of the latter was not objectionable. Quick lime forms new combinations with putrescent substances, and in thus combining, throws off effluvia, which though different from the products of putrescent matter alone, are still disagreeable and offensive. Mild lime on the contrary absorbs and preserves every thing—or at least prevents the escape of any offensive odor being perceived. Whether putrescent vegetable matter is acted on in like manner by calcareous earth, cannot be as well tested by our senses, and therefore the proof is less satisfactory. But if it is true that calcareous earth acts by combining putrescent matters with the soil, and thus

preventing their loss, (as I have endeavored to prove in chapter viii.) it must follow that to the extent of such combination, the formation and escape of all volatile products of putrefaction will also be prevented. But it will be considered that the most important inquiry remains to be answered: Has the application of calcareous manures been found in practice decidedly beneficial to the health of the residents on the land? Long experience, and the collection and comparison of numerous facts, derived from various sources, will be required to remove all doubts from this question; and it would be presumptuous in any individual to offer as sufficient proof, the experience of only ten or twelve years on any one farm. But while admitting the insufficiency of such testimony, I assert, that so far my experience decidedly supports my position. My principal farm, until within some four or five years, was subject in a remarkable degree to the common mild autumnal diseases of our low country. Whether it is owing to marling, or other unknown causes, these bilious diseases have since become comparatively very rare. Neither does my opinion in this respect, nor the facts that have occurred on my farm, stand alone. Some other persons are equally convinced of this change on other land as well as on mine. But in most cases where I have made inquiries as to such results, nothing decisive had been observed. The hope that other persons may be induced to observe and report facts bearing on this important point, has in part caused the appearance of these crude and perhaps premature views.

Even if my opinions and reasoning should appear sound, I am aware that the practical application is not to be looked for soon; and that the scheme of using marl in towns is more likely to be met by ridicule, than to receive a serious and attentive examination. Notwithstanding this anticipation, and however hopeless of making converts either of individuals or corporations, I will offer a few concluding remarks on the most obvious objections to, and benefits of the plan. The objections will all be resolved into one—namely the expense to be encountered. The expense certainly would be considerable; but it would be amply compensated by the gains and benefits. The general use of marl as proposed for towns, would serve to insure cleanliness, and purity of the air, more than all the labors of boards of health and their scavengers, even when acting under the dread of approaching pestilence. Secondly, the putrescent manures produced in towns, by being merely preserved from waste, would be increased ten-fold in quantity and value. Thirdly, all existing nuisances and abominations of filth would be at an end, and the beautiful city of Richmond (for example) would not give offence to our nostrils, almost as often as it offers gratification to our eyes.—Lastly, the marl after being used until saturated with putrescent matter, would retain all its first value as calcareous earth, and be well worth purchasing and removing to the adjacent farms, independent of the enriching manure with which it would be loaded. If these advantages could indeed be obtained, they would be cheaply bought at any price likely to be encountered for the purpose.

(From the New England Farmer.)

WATER, ITS USE IN VEGETATION, &c.

We have been requested by a subscriber to give some remarks on the uses of water in agriculture and the means of its artificial application.

In the first place we would remark that it is not advisable to let theoretical speculations on the advantages of irrigation induce a cultivator to incur great expenses in counteracting natural deficiencies of soil, &c. Where grounds are free from perennial springs or low marshes, excess of moisture, may, with proper management, be turned to certain profit. It is not very difficult to make provision to drain off an excess of water; but where the soil is naturally too dry, moisture cannot often be supplied by art, in sufficient

quantities for agricultural purposes, but by an expense, entirely inconsistent with the economy of farming.

Perhaps the best possible mode of watering plants in most cases is to attract the requisite moisture from the atmosphere. That water exists in the atmosphere may be proved as follows:—If some of the salt called muriate of lime, that has been just heated red, be exposed to the air, even in the driest and coldest weather, it will increase in weight and become moist; and in a certain time will be converted into a fluid. If put into a retort and heated, it will yield pure water; will gradually recover its pristine state; and, if heated red, its former weight; so that it is evident, that the water united to it was derived from the air. And that it existed in the air in an invisible and elastic form, is proved by the circumstance, that if a given quantity of air be exposed to the salt, its volume and weight will diminish, provided the experiment be correctly made.

The quantity of water which exists in air as vapor, varies with the temperature. In proportion as the weather is hotter, the quantity is greater. At fifty degrees of Fahrenheit air contains about one-fiftieth of its volume of vapor; and as the specific gravity of vapor is to that of air nearly as ten to fifteen, this is about one-seventy-fifth of its weight.

At one hundred degrees, supposing that there is a free communication with water, air contains about one fourteenth part of vapor in volume, or 1-21st in weight. It is the condensation of vapor by diminution of the temperature of the atmosphere, which is probably the principal cause of the formation of the clouds, and of the fall of dew, mist, snow or hail.

Now in order to moisten the earth in a dry time we have only to obtain moisture from the air, which is a great reservoir of moisture, existing in most abundance, in the hottest weather. This moisture can only be artificially obtained by attraction or causing it to be absorbed by some other substance. It may be absorbed either by the soil, the manure, or the plants themselves for whose nourishment it is required. With regard to the power of the soil to absorb water, by what is called cohesive attraction, this depends in some measure on the division of its parts. If the earth be hard, and its particles as it were welded together, it will attract but little moisture from the air, dews, &c. and even the rains will run off without penetrating the surface. Thus a foot-path over a field in dry weather will be dryer than the untrodden soil on its borders, and the more you stir a soil, other things being equal, the less will it suffer by drought.

Sir Humphry Davy observed that "the power of the soil to absorb water by cohesive attraction depends in a great measure upon the state of division of its parts; the more divided they are, the greater is their absorbent power. The different constituent parts of soils likewise appear to act even by cohesive attraction, with different degrees of energy. Thus vegetable substances appear to be more absorbent than animal substances; animal substances more so than compounds of alumina and silica [clay and sand] and compounds of alumina and silica more absorbent than carbonates of lime and magnesia: their differences may, however, possibly depend upon the differences in their state of division and the surface exposed.

"The power of soil to absorb water from air is much connected with fertility. When this power is great, the plant is supplied with moisture in dry seasons; and the effect of evaporation in the day is supplied by the absorption of aqueous vapor from the atmosphere, by the interior parts of the soil during the day, and by both the exterior and interior during the night. The stiff clays approaching to pipe clays in their nature, which take up the greatest quantity of water when it is poured upon them in a fluid form, are not the soils which absorb most moisture from the atmosphere in dry weather. They cake and present only a small surface to the air; and the vegetation on them is generally burnt up almost as readily as on sands. The sods that are most efficient in supplying

plants with water by atmospheric absorption, are those in which there is a due mixture of sand, finely divided clay, and carbonate of lime, with some animal or vegetable matter, and which are so loose and light as to be easily permeable by the atmosphere.

From the foregoing premises, it is apparent that one mode of watering plants, is to hoe them and keep the ground in a finely pulverized state about their roots. The leaves of living plants likewise attract the water held in solution in the atmosphere. Some vegetable increase in weight from this cause, when suspended in the atmosphere and unconnected with the soil; such are the house-leek, and different species of the aloe. In very intense heats, and when the soil is dry, the life of plants seems to be preserved by the absorbent power of their leaves; and it is a beautiful circumstance in the economy of nature, that aqueous vapor is most abundant in the atmosphere when it is most needed for the purposes of life, and that when other sources of supply are cut off this is most copious.

Dr. Deane observed, "vegetables that are newly transplanted, as they have their roots more or less diminished or otherwise injured, often need watering till they have taken new root. But this should be done with caution. If a dry season follow the transplanting, let them be watered if they appear to droop, only on evenings, and in cloudy weather, and with water that has been exposed one day, at least, to the shining of the sun; not with water directly from a well, or a cold spring, as it will give a chill to the plants. Only a small quantity should be applied at once, that it may have an effect similar to that of a refreshing rain. For water applied too plentifully, sometimes washes away the finest of the mold from the roots; or makes little cavities about them which admit too much air.

"In a dry season, whole gardens sometimes need watering; and in doing it the above precautions are to be regarded. They are happy who have a piece of standing water in their garden, or a rivulet near at hand, from whence the garden may be watered without much labor."

A copious supply of water is very essential to a good kitchen garden. Loudon remarks, that "many kitchen crops are lost, or produced of very inferior quality, for want of watering. Lettuces and cabbages are often hard and stringy; turnips and radishes do not swell; onions decay, cauliflowers die off; and in general, in dry seasons, all the *crucifera* (plants whose flowers consists of four petals placed in the form of a cross) become stunted or covered with insects even in rich and deep soils. Copious waterings in the evenings, during the dry season, would produce that fulness and succulency, which we find in vegetables produced in the low countries, and in the Marsh Gardens at Paris, and in England at the beginning and latter end of the season. The vegetables brought to the London market from the Neat's houses, and other adjoining gardens where the important article of watering is much more attended to than in private country gardens, may be adduced as affording proofs of the advantage of the practice."

With regard to the quality of water used for irrigating land and watering plants there has been some disagreement, some preferring hard and others soft water. But in this as in many other cases no general rules can be laid down which do not admit of many exceptions. Sir Humphry Davy says, "when the water used in irrigation has flowed over a calcareous bed, it is generally found impregnated with carbonate of lime; (the most common cause of what is called hardness in water;) and such water tends in that respect to ameliorate a soil in proportion as any of the modifications of lime and charcoal were deficient; but where these are already in excess, water charged with a lime sediment should be withheld; while water impregnated with sand, clay, gypsum or particles of iron would be beneficial.

"Common river water generally contains a certain portion of the constituents of vegetable and animal

bodies; and after rains this portion is greater than at other times; it is habitually largest, when the source of the stream is in a cultivated country.

"In general, those waters which breed the best fish are the best fitted for watering meadows; but most of the benefits of irrigation may be derived from any kind of water, provided the soil be not already over charged with the prevailing ingredients in the deposit left by the water; and provided, on the other hand, that the matter of the soil and the matter of the deposit are not pernicious when combined. These are the general principles.—1. That waters containing ferruginous impregnations [particles of iron] tend to fertilize a calcareous soil. 2. Ferruginous waters are injurious on a soil which does not effervesce with acids, which is one of the tests of the presence of lime. 3. Calcareous waters which are known by the earthy deposit they afford when boiled, are of most use on siliceous (sandy) soils, or other soils containing no considerable portion of carbonate of lime."

(From the New York Farmer.)

ON THE CULTIVATION OF RYE.

Haverhill, Sept. 22, 1832.

To the Trustees of the Essex Agricul. Society:

Gentlemen,—Having for some years past been more than commonly successful in raising large crops of winter rye by a process of cultivation, which, I believe, is entirely new, I have been induced, by the suggestion of some gentlemen whose judgment I very much respect, to submit for your consideration a statement of the mode of culture, with the produce. And that the success of the experiment this season may not appear to be altogether accidental, it will, perhaps, be as well to communicate the result of the process for the three or four previous years.

The land on which the experiment has been conducted is situated on the Merrimack, about a mile and a half east of Haverhill bridge; and came into possession of my father in 1827. The soil is a sand, approaching to loam as it recedes from the river. Perhaps the term *plain land* (by which it usually passes) will better convey an idea of the quality of the soil. It is altogether too light for grass. The crops we find most profitable to cultivate on it are winter rye, Indian corn, potatoes, and to some extent turnips. Oats might probably be raised to advantage, were it not that the land is completely filled with the weed commonly called charlick, which renders it entirely unfit for any spring crop, excepting such as can be hoed. The crops of rye, on the neighboring soil of the same nature, vary, I believe, from seven or eight to twelve or thirteen bushels per acre, according to the cultivation, and their approximation to the river. We usually raise on land from thirteen to thirty bushels of Indian corn per acre. Potatoes are very good in quality, but the quantity is quite small; not sufficient to be profitable, were it not that the land is very easily cultivated.

In the summer of 1827, we sowed three bushels of winter rye near the river, on about two acres of land, which produced twenty-eight bushels.

In 1828, we sowed four bushels on four acres of land running the whole extent of the plain from the river. This piece was sowed in the spring with oats; but they were completely smothered with charlick, and about the middle of June, the whole crop was mowed to prevent the charlick seeding. By about the middle of August, a second crop of charlick having covered the land, it was ploughed very carefully, in order completely to bury the charlick; and then suffered to remain until the 15th of September, when we began sowing the rye in the following manner: A strip of land about twelve yards wide was ploughed very evenly, to prevent deep gutters between the furrows, and the seed immediately sown upon the furrow and harrowed in. Then another strip of the same width, and so on until the whole was finished. We found the oat stubble and charlick entirely rotted, and the land appeared as if it had been well manured, though

none had been applied to this part since it had been in our possession. The rye sprung very quick and vigorously, having evidently derived great benefit from being sown and sprouted before the moisture, supplied by the decaying vegetable matter in the soil had evaporated to any considerable extent. This crop produced one hundred and thirty-three bushels.

In 1829, the charlick was suffered to grow on the land appropriated to rye, until it had attained its growth and was in full blossom. The land was then ploughed very carefully, and the charlick completely covered in. In a short time a second crop appeared more vigorous than the first. This also was allowed to attain its growth, and then ploughed in as before. A third crop soon appeared, which of course was destroyed, when the land was again ploughed for sowing about the middle of September. This piece of land was a parallel strip running from the river, and containing two acres. Two bushels of rye were sowed. The crop presented a remarkably promising appearance, and yielded seventy-four and a half bushels.

In 1830, the land appropriated to rye included nearly all the lighter part of the soil, and owing to a pressure of business was not attended to as we could have wished. It was ploughed in the early part of the summer. But harrowing to destroy the weeds was substituted for the second ploughing. This, and the unusual blight which affected all the grain in this part of the county, led us to anticipate a small crop. It yielded, however, fifteen bushels to the acre.

The land on which the crop of rye was raised the present season had for the three or four previous years been planted with Indian corn; and owing to the extent of our tillage land, we have not been able to apply more than four or five loads of manure to the acre this season. The charlick was suffered to attain its growth as usual; and on the 18th and 19th of June, it was carefully ploughed in. The second crop was ploughed in on the 6th and 7th of August. On the 14th and 15th of September it was sowed in the usual manner, namely, a small strip of land was ploughed, and the seed sown immediately upon the furrow, and then harrowed in. Then another strip of land was ploughed, and so on until the whole was completed. One bushel per acre was sowed as usual. The seed was originally obtained from a farmer in this vicinity, and I suppose is similar to that which is generally used. We have never prepared our seed in any manner, but have directed our attention solely to the preparation of the land; and to this we attribute our success. Owing to the unusual severity of the winter, the crop was considerably winter killed, but recovered very soon in the spring, excepting in the mid-furrows. There, as the land lies very level, the water settled, and so completely destroyed the rye that they continued bare the whole season. This would of course cause some diminution in the crop: perhaps a bushel or two. The rye was reaped at the usual season, and, as the weather was favorable, immediately put into the barn. The land contained one acre and thirteen rods, and yielded *forty six bushels and three pecks. A remarkably fine sample.*

In entering a claim for your premium, I would ask your attention particularly to the process of cultivation. It is I believe entirely new, and capable of general application.

Sowing the seed immediately after the plough we consider very advantageous to the crop. The soil being then moist, causes the seed to spring immediately, and gives a forwardness and vigor to the plants which they ever after retain.

The process of ploughing in three crops of weeds before the seed is sown, very much enriches the soil. It would be altogether unnecessary to attempt to refute the notion, that by such a process nothing more is applied to the soil than was before derived from it. If one could not discover by the light which chemistry has shed upon the subject of agriculture, sufficient reasons for the contrary conclusion, observation,

one would think, would be sufficient to convince any intelligent man of the fact.

And here I would suggest, that I do not consider the experiment, as we have conducted it, quite complete. To render it more so, in the first place, in ploughing in the weeds, I would not turn a furrow after the dew had evaporated. I have no doubt but that a large portion of that fertilizing quality in the soil, which (during the summer months) is continually exhaled from the earth, is by the dew brought again within our reach, and it would be wise to avail ourselves of the opportunity of again burying it in the soil. And in the second place, I would by all means use a heavy roll after each ploughing. It would fill all the cavities left by the plough, and by pressing the soil more closely to the weeds, at once hasten their decomposition and very much retard the evaporation from the soil.

But the land is not only very much enriched by this process. There is, I conceive, no method by which it can be so effectually cleaned. Three times during the season a fresh surface is presented to the atmosphere, and each time, as the decaying vegetable matter increases in the soil, so is the exciting cause augmented to make a more vigorous effort. We have in this manner gone over nearly all our land which is infested with charlick, and the diminution of the weeds is quite sufficient to warrant the expectation, that in a few years it may be comparatively eradicated.

Very respectfully, JOHN KEELY.

The under-signed having assisted in measuring the rye, an account of which is given above, hereby certify that the quantity is as there stated, namely, forty six bushels and three pecks.

JOHN KEELY,
THOMAS E. KEELY,
SAMUEL THOMPSON.

Haverhill, Aug. 1, 1832.

I have this day measured a lot of land belonging to Mr. Keely, on which is a crop of rye, and find it to contain one acre and thirteen rods.

C. WHITE, Surveyor.

At a meeting of the Trustees of the Essex Agricultural Society, January 1, 1833, the foregoing statement having been read and examined,

Voted, That the first premium offered for the cultivation of rye be awarded to Mr. Keely.

Attest, J. W. PROCTOR, Sec'y.

(From the Newbern Spectator.)

GAMA GRASS.

The grass which passes under this name has acquired a considerable degree of celebrity, and promises to become of much importance to the agricultural interests of the southern states. I say to the interests of the southern states, because the northern and western portions of our country are already so well provided with a variety of valuable grasses suited to their climate and soils that to them the acquisition of one more can be of little importance, if indeed the one we are now considering should prove to be adapted to a northern climate. Whereas, in the alluvial portions of the southern states, I believe that neither clover, timothy, orchard grass, herd's grass, nor any other of the grasses derived from northern climates, have ever proved, or ever will prove extensively beneficial. The consequence is, that throughout this extensive and fertile portion of country no hay of any kind is made,* and the only native product relied upon as provender for horses and cattle generally, are the dried blades of Indian corn. (Zea mays.) Charleston and Savannah import northern hay, and even in the interior as high up as Columbia and Augusta you meet with it!

* Occasionally a little hay is made in the south from what is called the "crab grass," (Eleusine indica.) But this grass will grow only in cultivated soils.

During the last summer and fall, while engaged in occasional investigations of the botany of this neighborhood, I found upon the shore of the Neuse two species of grasses belonging to the genus *Tripsacum*, to wit: the *Tripsacum dactyloides*, and the *T. monostachyon*. At that time I had not seen the "Gama grass," nor any of the publications relating to it, and I therefore did not know, what I have since ascertained, that one of these species is probably the famous "Gama grass." During the last winter I saw in the possession of a gentleman in Florida, a few of the seeds of the Gama grass, which he had received from abroad, and he informed me that he had found the same grass growing native in Florida. I immediately recognised them as belonging to one of the species of *Tripsacum*, apparently the *T. monostachyon*; but I was held in some doubt on account of a third species of this genus, mentioned and described by Michaux, in his North American Flora, under the title of *Tripsacum cylindricum*, and found by him in Florida. This species, like the *T. monostachyon* has cylindrical spikes, while the *T. dactyloides* has them flattened on one side, and rounded on the other, but differing from both in the circumstance of having its flowers "hermaphrodite." On looking into Loudon's "Encyclopedia of Plants" I found mentioned a species growing in the West Indies under the title of *Tripsacum hermaphroditum*, which I could scarcely doubt to be identical with the *T. cylindricum* of Michaux having hermaphrodite flowers, a species which Elliott suspects to belong to the genus *Rotbolla*, and which Nuttall, probably from its ambiguous character, has not mentioned at all. But the Encyclopedia of Plants further remarks upon the genus *Tripsacum*, that they are grasses, used for provender in the West India islands, an expression somewhat loose, as only one species of the genus is said to grow in the West Indies, but indicating the opinion of the writer that all the species might be employed for that purpose. And to this conclusion I have been led by my subsequent inquiries of those who have cultivated the grass. For one gentleman assures me that the grass which he cultivates as the Gama grass has the spikes aggregated, and is, therefore, the *Tripsacum dactyloides*; another that the spikes of his grass are cylindrical and solitary, and is therefore, the *T. monostachyon*, it indeed, it be not the *T. cylindricum* of Michaux. I left Florida before the grass there cultivated had evolved its spikes, and therefore, could not ascertain to which of the species it belonged, though it must be to one of the last two.—Which of the three species is the true *Samon Pure*, I will not undertake to determine, but my conclusion is that all of them may be employed with almost equal benefit. Perhaps the two last species may be less rough than the first, and I apprehend, that if the grass be not frequently cut, it becomes too rough, and will be refused by horses, if not by black cattle. But the great value of the grass is, that it grows with great rapidity and luxuriance even in the sandy soils of the south, if moderately rich, and bears cutting, it is said, every month during the summer and fall. The published accounts say, that it will yield from seventy five to ninety tons the acre; and I learn from a gentleman who cultivates it, (W. B. Meares, Esq. of Wilmington,) that it does well both in sandy and clay soils. It appears that one of the species is found native in Florida, and the West India islands, and the two others along the Atlantic coast from the Delaware river to South Carolina, and probably to Florida, and also, "in the vast prairies of the western states," as Mr. Nuttall informs us. It is, therefore, probable that this is one of the few valuable grasses that adapt themselves to every climate and every soil.

Those among us who wish to obtain it, have only to search for it during the ensuing fall along our river shores. If they have once seen and observed the seeds of one of the species they will be in no danger of mistaking the plant, for it has a decided character.

H. B. C.

HORTICULTURE.

(From the Southern Agriculturist.)

ON THE DURATION OF VITALITY IN GARDEN SEED.

Rocky Grove, Abbeville District, March 19, 1833.

Dear Sir,—I send you a few extracts from my note book on gardening, which you can use as you think proper.

Question—How many years old will Carolina grown seeds vegetate in Carolina?

Answer—Cabbage, 2 years—not one the third year; two experiments.

Civie Beans,	2 years,	do.	do.
Musk Melon,	4 years, not one	the fifth year.	
Cucumbers,	4 years,	do.	do.*
Water Melons,	4 years, not tried	further.	
Pumpkins,	4 years,	do.	
Squashes,	3 years,	do.	
Snap Beans,	2 years,	do.†	
Carrots,	2 years,	do.‡	
Okra,	3 years,	do.	
Tomatoes,	3 years,	do.	
Turnip,	5 years,	do.	
Radish,	3 years,	do.	
Onions,	2 years,	do.	
Lettuce,	3 years,	do.	
Endive,	3 years,	do.	
English Peas,	2 years,	do.	
Water Cresses,	2 years,	do.	

I have observed a difference of ten days in sprouting, between old and new seed in favor of the latter; the old seed sometimes takes fifteen days to vegetate. Respectfully, THOMAS PARKER.

(From the London Morning Chronicle, May 28.)

LONDON HORTICULTURAL SOCIETY.

On Saturday, the spring exhibition of flowers and fruits took place at the Gardens of the Society, near Turnham green. This exhibition is not on the same plan as the fetes which have formerly been held in these grounds, but is simply what it professes to be, an exhibition of choice flowers and fruits, but on a more appropriate spot than that in which similar exhibitions were heretofore held, viz: the rooms of the society. A military band, however together with the performances of the Tyrolese Minstrels, were an agreeable addition to the entertainment, whilst, for the convenience of those who wished to gratify other senses than those of sight and hearing, refreshments of a suitable kind were provided.

The weather was particularly auspicious, and the grounds, which are very extensive, and are laid out with considerable taste, afforded a really delightful promenade. The various rare and beautiful plants with which they abound, appear to be in that flourishing condition which can alone result from skill and constant attention. We may, however, be pardoned if we hint our regret at the absence of many of those beautiful productions of Flora which are our more

* Cucumber seed, five years old, planted in a common garden soil—not one came up—planted in a dung hill, and watered morning and evening, came up perfectly well on the fifth day.

† In filling up the cracks of a log-house with clay in this neighborhood, a small bag of snap beans was accidentally enclosed between two logs in the clay. This clay was removed fifteen or twenty years after, when the bag of beans being discovered, they were planted by way of experiment, and the greater part of them vegetated.

‡ Three small beds of carrots sowed by way of experiment in June. Bed No. 1, was watered in the evenings and afforded a fair crop of carrots. Bed No. 2, watered morning and evening—scalded by the sun and destroyed. Bed No. 3, watered morning, noon and evening—these advanced in growth rapidly ahead of No. 1, and were remarkably large and fine.

familiar acquaintances. These might be interspersed with great effect, and would break that somewhat formal appearance which strikes the eye of the otherwise well pleased spectator. To admire only what is rare and costly, and to despise that which is really beautiful, because it is common and easy of attainment, is the mark of a vitiated taste—a taste in the gratification of which there is but little real pleasure, and which can only be compared to the sickly enjoyments of the epicure, who stimulates his jaded appetite with rich sauces till he loses all relish for the plain wholesome food essential to health. Let us not be misunderstood. We are far from disapproving of the cultivation of exotics. To obtain by art what nature has denied—to overcome the inaptitude of our soil, or the uncongenial temperature of our atmosphere—to collect within one small circle the various gifts of Flora to various nations and various climes—is an employment of wealth, both honorable and useful, and affords an innocent and delightful recreation, calculated to refine the taste, purify the affections and enlarge the understanding. It is, indeed, no small pleasure to behold the rich trees and flowering shrubs of brighter skies and more genial climates mingled with the equally, though differently, beautiful productions of the frozen regions, and to see them, not sighing like drooping exiles for their home, but strong, healthy, and vigorous—their native hues unfaded, and their native fragrance undiminished.

The exhibition of Saturday was, on the whole, one of the best we have seen, and considerable improvement was to be discovered in several of the new varieties. To particularize, where all was excellent, might appear invidious; but we cannot help referring to a few specimens by which we were particularly attracted—Smith's Noisette rose, exhibited by Colley and Hill, was especially admired. The same tribute was also paid to some very fine specimens of *Calceolaria*—the *Calceolaria suberecta*, of Mr. Lowe, and the *Calceolaria corymbosa hybrida*, of Mr. J. H. Palmer, as well as to Mr. Buck's pinks. The various specimens of *Cactus* were uncommonly fine. *Ericas*, *azaleas*, *rhododendrons*, *geraniums*, *roses* and *heartsease* were to be found in every variety, and in most beautiful condition; but in the tulips we were disappointed. It is, however, but justice to say, that had the exhibition taken place a fortnight sooner, there probably would have been no reason to complain on this head. Specimens of fruit, of course, could not be expected to great abundance, yet there were strawberries, (Keen's seedlings, and very fine,) raspberries, grapes, melons, one peach, and forty-eight apricots, forced without fire, by Mr. Labouchere.

The great silver medal was awarded to J. H. Palmer, Esq. and Banksian medals to Messrs. Brown, J. Lee, Colley and Hill, Chandler & Son, G. Mills, Labouchere, Water and Colvill. The gardens were filled with beautiful and elegantly dressed ladies, and many persons of high rank and fashion were present.

The decided success of this mode of exhibiting will, doubtless, ensure its repetition. We shall be glad of the occasion to repeat our visit, trusting, however, that our gratification will be shared with a yet larger number of visitors than on the present occasion, and will be increased by more extended views of the benefits likely to result from the society's exertions.

RHUBARB PIE.—The Rhubarb root, which makes such rich and delicious pies, will grow doubly well by placing an empty barrel over it. A friend of ours had two plants by the side of each other. To test the fact, he placed a barrel over one, and left the other uncovered. At the expiration of a fortnight, the covered one had extended itself beyond the top of the barrel, while the other by its side had grown, perceptibly, but very little. One plant served in this manner, will supply the largest family with materials for delicious Rhubarb pies.

[Northampton Courier.]

RURAL ECONOMY.

(From the Columbia Telescope.)

CURE FOR THE BITE OF THE RATTLESNAKE.

We have been politely favored with the following correspondence, which we are glad to be the means of making public. The name of the gentleman who has been instrumental in bringing the plant alluded to, to the knowledge of the faculty, is suppressed in obedience to his own feelings of delicacy on the subject—but we can assure the public that there is no man in the world upon whose veracity more implicit reliance may be placed.

Columbia, Aug. 28, 1829.

Dear Sir,—The plant you was so obliging as to send me in the box came at a propitious season (being now in blossom) for ascertaining with precision what plant it is. It is the plant known among botanists by the name of the *Asclepias verticillata*, and belongs to the same family of plants with the well known butterfly weed, or pleurisy root, with yellow blossoms, common in our fields and known to the botanists, by the name of *Asclepias decumbens*.

The *Asclepias* is an extensive family of plants, many of which have long been recognized as medicinal. This fact together with the strongly marked instances of its efficacy in the bites of snakes, which have happened within your immediate observation, seem to me to entitle it to more consideration, and to render it deserving of farther attention on trial than the reputed remedies of this sort generally.

It might probably, therefore, be subserving the cause of humanity, if you would be so good as to make a detailed, but brief statement of the facts in your possession, and I will endeavor to draw attention towards the subject by procuring its publication in the papers. As this is a dangerous season of the year for the bites of snakes, the remedy by being made public may be speedily tested; and if really equal to its apparent powers in the cases witnessed by yourself, it may mitigate much suffering and save some lives.

I anticipate your unwillingness to having your name in the papers on slight occasions, and therefore, if you think proper, it shall not appear. It will be enough to invite public attention to the remedy, and then let it stand or fall according to its own merits.

Very respectfully, dear sir, yours,

JAMES DAVIS.

DR. JAMES DAVIS.

September 4, 1829.

Dear Sir,—Yours of the 28th ult. I have received, requesting a brief statement of the cases which I have witnessed of the efficacy of the plant which I sent you, in curing the bite of the rattlesnake.

About ten years ago my son was bitten on the instep, by a ground rattlesnake, about dark on Friday night, and every remedy which I then knew, such as hart-horn, camphorated spirits, oil, &c. was applied without effect.—He continued to grow worse, and on Saturday night, his leg was so swollen, that the skin burst in three places, on the calf of his leg, near the knee; and mortification, as far as I could judge, appeared to have commenced.—At this time a friend of mine, by whom this plant was known, called, and advised me to try it. I did so, and found that it gave him immediate relief. In a few hours, he was perfectly well, except the ulcers on his leg: they were afterwards attended to and dressed as common ulcers, and healed as speedily as any sores I had ever witnessed.

A year or two afterwards, a negro boy was bitten, by one of the same kind of snakes, on the foot. I procured the plant the same day, and administered to him, not however before the foot and leg were greatly swollen. He was, also, instantly relieved, and next morning went to his work with the rest of the negroes, perfectly well; though his foot and leg remain-

ed swelled for several days. He never complained of any pain or inconvenience from the snake bite afterwards.

A third case happened a few years since.—My daughter, a child, then about six years old, was bitten by one of the same kind of rattlesnakes, on the finger. In this instance, the application was made within two hours after the wound was inflicted. Her hand, at the time she took the medicine, was prodigiously swelled; it was nearly as round as her arm, and she was screaming with pain. On taking the tea, she became easy, and within fifteen minutes was fast asleep and awoke perfectly restored; and before the next morning the swelling had entirely abated.

A tea is made of the plant, root and top, and given to the patient, in broken doses, until it vomits him; he then goes to sleep, sweats profusely, and awakes quite well; at least this has been the effect in each of the above stated cases. I have never used more than a dozen plants in any one case. Yours, &c.

MISCELLANEOUS.

(For the American Farmer.)

REMARKS MADE ON READING BARON CUVIER'S "ANIMAL KINGDOM."

In an introductory discourse, delivered before the Literary and Philosophical Society of New York, the late Governor CLINTON, speaks of "the fanciful system of the Arabian metaphysicians, adopted by Pope, in his Essay on Man:

"From Nature's chain whatever link you strike,
Tenth, or ten thousandth, breaks the chain alike."

And he adds: "this doctrine of a *chain of being* is equally a superstition of philosophy, and a dream of poetry. Many links have been broken in this imaginary chain, many species have been destroyed, and yet the harmony of nature has not been disturbed."

On this subject, CUVIER remarks: "The pretended chain of beings, as applied to the whole creation, is but an erroneous application of those particular observations, which are only true when confined to the limits within which they were made. It has, in my opinion, proved more detrimental to the progress of Natural History in modern times, than it is easy to imagine." McMurtrie's Translation, vol. i. p. 17.

"*Sciurus volucella*.—(The American flying squirrel.) It lives in troops in the prairies of North America." Vol. i. p. 137.

This is doubtless a mistake. In a prairie, the flying squirrel would be in a helpless condition. It has no wings to rise with. Its membranes, like the rudder of a ship, can impart no motion. It is only when it is in motion, that these, like a rudder, by pressing against the air through which it passes, retards its descent and guides it on its course. It would, therefore, avoid the prairies as long as it retained a sense of its own faculties; and it is wonderful how well every animal understands its own powers, and the situation for which nature designed it.

But it is not from reasoning alone that I infer this mistake. I have only seen the flying squirrel in the woods, having often very unintentionally ejected him from his hollow tree, when we have been cutting timber. Instead of a "troop," I have never seen more than what I supposed to belong to one nest. As soon as they recover from the concussion, they run up the first tree that they come to, and often from a height of seventy or eighty feet, launch into the air, through which they rapidly glide, towards another tree, assuming as the velocity increases a more horizontal direction.

Since writing the above, I find that Dr. Godman, in his "American Natural History," says: "Their peculiar construction and habit render them very unfit for living on the ground;" and consequently unfit for inhabiting prairies. He adds, "occasionally large troops are seen together, and their sailing

leaps have been said present to the inexperienced the appearance of a large number of leaves blown off the trees." It is to be inferred from this expression that Dr. Goldman himself never saw them on those sailing excursions. It would be very strange indeed, if he had; for the flying squirrel is a nocturnal animal, only travelling in the day-time, like the owl, when he can do no better. I am a woodsman, and have associated with old hunters for years, yet I have neither seen nor heard of such a "troop."

"*Chrysochloris asiaticus*.—(The golden mole.)—Is the only known quadruped that presents any appearance of those splendid metallic tints that adorn so many birds, fishes, and insects. Its fur is a green changing to a copper or bronze." P. 89.

"*Mus rattus*.—(The black rat.) of which no mention is made by the ancients, and which appears to have entered Europe in the middle centuries." P. 143.

"*Mus decumanus*.—(The Norway or brown rat.) which did not pass into Europe till the eighteenth century; and is now more common in large cities than the black rat itself. It is larger than the latter by one-fourth, and differs from it also by its reddish brown hair.

"It appears to belong to Persia, where it lives in burrows. It was not till the year 1727, that after an earthquake, it arrived at Astracan by swimming across the Volga."

It is truly wonderful that those animals kept quiet ever since the flood, till that period; and that then they should overrun the world in the course of one century; on such subjects, however, we have no higher authority than Baron Cuvier.

I have heard old people say, that black rats were common till the Norway rats arrived and dispossessed them.

AN AMERICAN FARMER.

(From the New York Farmer.)

CLIMATE, PRODUCTIONS, &c. OF COLOMBIA.

The following extracts from a letter from a highly respectable and intelligent gentleman, long a resident in Colombia, will be read with interest. The means of knowing and observing the condition of the country were open to the writer in an unusual degree, and the accuracy of his statements may be relied upon.

The population here is mixed; there are all colors, and all shades of colors, to be found; there is the pure white Castilian, the pure Indian, the pure African, and every hue that could result from an amalgamation of the three. The people are naturally very talented and very amiable, and of fine manners, the ladies particularly; and they are besides very beautiful, which I can say without offending any of my own charming countrywomen—for when I choose to compliment a lady here, I tell her that I consider her worthy of being a North American. I could say nothing, as I conceive, more flattering. They are besides almost all patriots, of much decision and energy of character; and the successful issue of the Revolution, and of the subsequent redemption of the country from the usurpation of Urdaneta, may be in no small degree imputed to the women of Colombia. They never despaired of the Republic; they suffered every thing that the remorseless cruelty of the Spaniards could inflict. But they suffered with the firmness of the Spartan matrons, and have even gone to the scaffold unshrinking and undismayed, repeating to the last that magic and hallowed word, *libertad, libertad*, (liberty, liberty.) Such are the women of Colombia. Good wives, good mothers, and good republicans,—if they have vices, they are redeemed by many virtues; and let it be recollected, as a potent apology for them, that they are heirs to the bad effects of the three hundred years' continuance of bad institutions, and that they have been parties and victims to a fierce and sanguinary conflict of twenty-two or twenty-three years, and that they are the children of a tropical climate.

In this country there is nothing more striking than

the astonishing variety of soil and climate and productions. The soil is very excellent in many parts, and adapted to the cultivation of every thing that grows. Three crops of corn may be gathered in the course of the year from the same ground in many places. The people cultivate sugar cane, cotton, coffee, cocoa, indigo, tobacco, a variety of grains, wheat, barley, rice, &c. &c., garden vegetables, and an almost infinite variety of delicious fruits. The state of agriculture is in a most lamentable and languishing condition, as you may infer from one fact amongst many. In the neighborhood of this place there is an abundance of wheat land; yet it is no uncommon thing to see very indifferent flour selling at the rate of thirty-five to forty dollars the barrel, and I will add, that I have seen Irish potatoes selling at three dollars the bushel; that was, however, when the city was besieged, and the supplies partially cut off, but still they are always extravagantly dear, although they are grown in almost all parts of this country, and are much superior to those of the United States.

As there are no seasons here excepting the wet and dry, the wet called the winter and the dry the summer, the productions of the soil are regulated by the climates. In what they call the cold climate, perhaps, from eight to twelve or thirteen thousand feet above the level of the sea, they grow wheat and other small grain, potatoes, aracachas, &c. &c. Corn does not do well. In the plain of Bogota, the elevation of which is about nine thousand feet, it requires nine or ten months for it to ripen. There the mercury in Fahrenheit's thermometer ranges, in the shade, from fifty to sixty-five; generally it is from fifty-six to sixty-two, or thereabouts. In the sun it is sometimes very warm; but flannel is worn throughout the year by all foreigners, and by many of the natives.

In what is called the temperate climates, with an elevation of four or five thousand feet above the sea, they grow cotton, sugar-cane, corn, potatoes, and various fruits. In those climates it is from twelve to fifteen degrees warmer than the cold. The next is the warm climate, but little elevated above the sea, where it is always excessively warm. The productions belonging to those climates are cocoa, coffee, cotton, sugar-cane, indigo, corn, with a few garden vegetables, and many kinds of fruit.

The facility of changing climate here surprises a North American at first. In the United States there can be no very decisive change without going to Mexico; a voyage or journey of some two or three thousand miles. Here you may leave in the morning a point, say twelve or thirteen thousand feet above the sea, where it will be equal to our worst March weather; at twelve you may be in a climate where the temperature is about equal to our May weather; and you may sleep at night in a climate equal to that of New Orleans, in its utmost fervor. This diversity of climate is a great convenience to the sick and to the valetudinarian. There are many delightful baths too, mineral and chalybeate, warm and tepid, which are very beneficial.

There are so many kinds of fruit, that it would require a sheet to enumerate them. The principal are oranges, pine-apples, cambres, grenadillas, which are very fine. There is also a fruit called the *chirimaya*,* which is designated here the queen of fruits, and which Humboldt says is worth a trip to this country to eat. All these, and many more, are very cheap. Apples and peaches they have too, but they are scarcely considered eatable by a North American. The art of engrafting and inoculating is but little understood and less practised, and without these there can be no good apples. The quantity of fruit and the cheapness of sugar lead to the custom, I presume, of making enormous quantities of sweetmeats, which

* *Chirimaya*, is the *Anona cherimolia*, v. *tripetala*, of botanists. The Editor of the American Farmer, has a fine plant of it, a present from Wm. Prince & Sons, of Flushing. It is a tender hot-house plant.—Ed. Amer. Farmer.

constitute a part of every meal, and in my judgment do much mischief.

Manual labor is but little relieved here by mechanism. There are but few labor-saving machines of any kind in the country, not even a cotton gin (or not more than one) or spinning jenny. The people are not fond of innovations, and are particularly hostile to those that might happen to interfere with their usual and hereditary occupations.

What I have written will serve to give you a slight knowledge of this country, of which it has been justly said, "God has done much for it, and man very little."

(From the New York Farmer.)

AGRICULTURE OF YUCATAN—TROPICAL PLANTS.

Consulate U. S. A. Campeche, May 25, 1833.

Sir,—I intended to fill this sheet with information concerning the simple agriculture of Yucatan, which, I have before stated, employs neither plough nor harrow, nor spade, nor rake, but as I have given a letter of introduction to the Senor Leal, a native cultivator of this peninsula, you will be able to acquire from him the few details relative to corn and cotton, cassava and the cane. By the by, according to Bernal Dean, the very name of Yucatan consists of two Maya words, which signify cassava field. Notwithstanding the apparent sterility of its rocky surfaces, it already produces sugar for exportation, although the first stalk of Otahentan cane was introduced only fifteen years ago. Indeed in the delicious climates of the tropics, vegetables seem to need scarcely any nourishment direct from the soil, and either ignorance or cowardice must have represented them as hostile to the health of the human race. As the South Carolina disturbance has prevented the passage of the bill reported in favor of my enterprise for domesticating tropical plants in the equally delightful atmosphere of Cape Florida, I most content myself here with the promise of J. Dubose, to receive and take care of the seeds and plants of which I have already forwarded to him there a great variety. The two greatest blessings of God to man, the plantain or Banana plant and the cocoa palm, are already flourishing at the Cape, with the orange and the lime. This summer will probably add to them the most productive farinaceous root on earth, the Jalsopher manhot, of which they extract in this peninsula the finest starch at the rate of two thousand five hundred to four thousand pounds the acre, which sells on the land where it is produced at less than two cents the pound, and in this city, with the costs of long land transportation, at three dollars and a half the one hundred pounds.—Add to this the fine flour which is produced in abundance by the mild root of the *Maranta arundinacea*, and sold in our apothecary shops as a luxury for the sick, under the name of arrow root, but which may be as well made a cheap subsistence for the well.—But I have not time even to sketch the outlines of the value of the various tropical plants which I have already forwarded, and which I trust in God will arrive in safety. Should a single vegetable of each species arrive at maturity at the Cape, I shall have conquered the most formidable obstacles to the complete success of my enterprise of domesticating tropical plants in the United States, by gradual acclimation.

Who dare assert that the Canary plantain will not extend to the Potomac?

Very respectfully, your obedient servant,

H. PERRINE.

FECUNDITY OF SHEEP.—Mr. E. P. Player, of Truro, has 10 ewes which brought forth in 1831, 21 lambs; in 1832, they had nine double births and one treble birth, making also 21; and in the present year, they have had 8 double births, one treble, and one single birth, making 20; in all 62 lambs from 10 ewes, in three years.—Falmouth (Eng.) Packet.

Prices Current in New York, July 20.

Beeswax, yellow, 18 a 20. **Cotton**, New Orleans, .14 a 16 $\frac{1}{2}$; Upland, .13 a .16; Alabama, .13 a .16. **Cotton Bagging**, Hemp, yd. .13 a .21 $\frac{1}{2}$; Flax, .11 a .15. **Flax**, American, 8 $\frac{1}{2}$ a 9. **Flaxseed**, 7 bush. clean, 15.00 a 15.25; rough, 13 00 a —. **Flour**, N. TALL MEADOW OAT GRASS SEED.

Just received at the American Farmer Establishment, 100 bushels Tall Meadow Oat Grass Seed, of first quality, just harvested and for sale, at \$2 50 per bushel, by
I. I. HITCHCOCK.

BAKEWELL SHEEP.

The Subscriber has become agent for John Barney, Esq. for the sale of his celebrated Bakewell Sheep. The stock now on hand for sale, is the following:
Eight or ten EWES, of good age and quality, at prices from \$40 to \$50.

About the first of September next, I shall have from the same flock six or eight Rams of this year's stock. Price \$50 each.

I shall have about the same time, from the flock of another celebrated breeder, a few Ram lambs—half Bakewell and half Southdown. Prices from \$30 to \$40 each. Address.
I. I. HITCHCOCK,
American Farmer Establishment.

DEVON CATTLE.

For sale by the Subscriber, one Devon Bull, ten months old; a handsome and promising calf. Price \$100. Also, a very beautiful and valuable Devon Heifer, two years old. Price \$175.

I. I. HITCHCOCK,
American Farmer Establishment.

TURNIP AND MILET SEEDS.

J. S. EASTMAN has in store prime fresh large White, Flat, and Red Top Turnip Seed, and fresh Milet Seed. Also seed Buckwheat, together with a general assortment of Garden Seeds and Harvest Tools, and Agricultural Implements generally. Also Fox & Borland's Patent Threshing Machines, with spring concaves.
July 12.

DURHAM SHORTHORN CATTLE.

I have for sale the following fine animals:

One full blood Bull, nineteen months old, by Gloster, out of a first rate full bred cow. He is not above middling size, but is a very beautiful and perfect animal. Price \$250.

One full blood bull, two years old—a very fine animal. Price \$250.

One full bred Heifer, two years old, now springing, but the calf will not be valuable, being (accidentally) by a common bull. She is a very fine Heifer, and will be sold for \$225.

Less than Full Blood.

One Bull, three years old, fifteen-sixteenths Durham; has been pronounced by good judges as fine an animal as was ever in the United States. He would be worth twice the price now asked for him if he had the other sixteenth of Durham blood. He will be sold for \$300.

One Bull, fifteen months old from good stock, seven-eighths Durham. Price \$225.

One Bull, three years old, half blood Durham, a very handsome animal, and from good stock. Price \$150.

One Cow, eight years old, seven-eighths Durham, a fine breeder, and now in calf by a full blood bull. Price \$100.

Three Milch Cows, half blood Durham, very good milkers, and of good size and form; calves from two to six weeks old. They will be sold for \$50 each.
Address
I. I. HITCHCOCK,
Amer. Far. Establishment.

TURNIP SEED.

For sale the following kinds of Turnip Seed, of the very first quality, at 75 cts per pound.

EARLY WHITE DUTCH.**GARDEN STONE.****WHITE FLAT. GREEN ROUND.****RED ROUND OR RED TOP.****WHITE NORFOLK. WHITE TANKARD.****YELLOW ABERDEEN. RUTA BAGA.**

And, as usual, a complete assortment of GARDEN SEEDS generally.

I. I. HITCHCOCK,

American Farmer Establishment.

HERBEMONT ON THE VINE AND WINE MAKING

Just published and for sale at the American Farmer Office and Seed Store, "A Treatise on the Culture of the Vine and on Wine Making in the United States. By N. Herbemont, of Columbia, S. C. Accompanied by remarks by the Editor of the American Farmer." Price, 25 cents

**TURNIP SEED, BUCKWHEAT, &c.**

400 lbs. White Flat and Red Top Turnip Seed.

100 lbs. Ruta Baga or Swedish do do

The above is of the present years' growth and raised under the immediate superintendence of Robert Sinclair, whose long success in raising this article warrants us in recommending it with the greatest confidence.

Also, Early White Dutch Tankard.

Yellow Bullock and Yellow Stone Turnip.

200 lbs. Fall Radish Seed, consisting of White and Black Spanish, Long White Summer, &c.

100 lbs. prime London Early York Cabbage Seed, Early George, Green Savoy, Flat Dutch, and many other kinds suitable for Fall Sowing.

IN STORE:

50 bushels Seed Buckwheat.

100 bushels Herds grass.

50 bushels Tall Meadow Oat Grass.

200 lbs. Canary Seed.

1500 lbs. Yellow Locust Seed.

150 lbs. Yellow Mustard Seed.

WANTED.—Clover, Timothy and Orchard Grass Seed, for which the highest price will be given.

July 13.

SINCLAIR & MOORE.

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street.
Ap. 26.

WANTED,

All kinds of GRASS SEED, for which a fair price will be given, by
I. I. HITCHCOCK,
American Farmer Establishment.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET—The flour and grain market continues to improve, as will be seen by our quotations. It must be borne in mind that our quotations of flour refer to fresh ground, and that the city mill's flour, quoted at \$6 50, contains a portion of new wheat. The wagon price of Howard street flour is \$5.87 $\frac{1}{2}$.

TOBACCO.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15 00; yellow and red, 9.00 a 15 00; yellow, 16 00 a 20 00.—Fine yellow, 18.00 a 25 00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3 50 a 5.00. The inspections of the week comprise 444 hlds. Md.; 57 hlds. Ohio; and 2 hlds. Penn.—total 503 hlds.

FLOUR—best white wheat family \$6.75 a 7.25; super; Howard-street, 6.00 a 6 1 $\frac{1}{2}$; city mills, 6.00 a 6.50; city mills extra 6.50 a —;—CORN MEAL bbl 3 62 $\frac{1}{2}$;—GRAIN, new red wheat, 1.20 a 1.28; white do 1.30 a 1.40 —;—CORN, white, 60 a 62, yellow, 63 a 64;—RYE, 69 a 70 —OATS, 28 a 31.—BEANS, 75 a 80—PEAS, 65 a 70—CLOVER-SEED 5.00 a —.—TIMOTHY 3.00 a —.—ORCHARD GRASS 3.00 a —.—Tall Meadow Oat Grass 2.25 a 2.50.—Herds', 1.00 a —.—Lucerne — a 37 $\frac{1}{2}$ lb.—BARLEY,—FLAXSEED 1.37 a 1.50—COTTON Va. 12 a 13 $\frac{1}{2}$ —Lou. 14 a 15—Alab. 12 a 13 $\frac{1}{2}$ —Tenn. 12 a 13; N. CONTENTS OF THIS NUMBER.

Editorial; Milch Cows—Dissemination of Trees and Plants, by Henry Perrine, Esq.—The Love of the Unseasonable—Domestic Silk—Foreign Markets—Supplementary Chapter to "An Essay on Calcareous Manures;" The use of Calcareous Earth recommended to preserve Putrescent Manures and to promote Cleanliness and Health—Water, its Uses in Vegetation, &c.—On the Cultivation of Rye—Account of the Gama Grass and its Culture in the South recommended—On the Duration of Vitality in Garden Seed—Exhibition of the London Horticultural Society—Rhubarb for Tarts—Cure for the Bite of the Rattlesnake—Remarks on Reading Baron Cuvier's "Animal Kingdom"—Climate, Productions, &c. of Colombia—Agriculture of Yucatan; Tropical Plants—Fecundity of Sheep—Prices Current of Country Produce in the New York and Baltimore Markets—Advertisements.

GENERAL**Agricultural and Horticultural Establishment:****CONFIRMING.**

A Seed and Implement Store, a General Agricultural Agency, and the Office of the AMERICAN FARMER, at No. 16 South Calvert street, Baltimore: in connexion with a Stock and Experimental Farm, Garden and Nursery in the vicinity.

☞ An extra number of the Farmer, containing a prospectus of the "Establishment," and a "Catalogue of Seeds," &c. kept for sale, shall be sent GRATIS to any person who shall by mail or otherwise furnish his address for that purpose.

AGENTS FOR THE FARMER.—All postmasters are requested to act as agents for the Farmer, and to require a strict compliance by subscribers with the terms, especially the third item. They are authorised to retain one dollar for each new subscriber, and ten per cent on all other collections. The list of special agents is published in the Farmer every third week. (Terms next week.)

☞ DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "I. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, AUGUST 2, 1833.

THE MOON.—It has been a question with us whether a periodical would not be as usefully employed in dissipating error as in disseminating information.—As it respects the influence of the moon on the weather, on crops, &c. we have no doubt that the general belief in it has done as much harm to the agricultural interest, as any other evil with which farmers and planters have to contend. How often do farmers omit a favorable season to plant a crop of potatoes, &c. because it is "not the right time of the moon." Many people will not kill hogs or beef, unless at a particular time of the moon. And when the "right time of the moon" does come, it is at least an equal chance that the state of the weather will not admit of these operations, or some other more necessary business must be performed, and of course they must be put off till the moon comes round again to the proper "time." Almost every body can tell what weather we are to have for the next four weeks, by looking at the new moon, and lay out their work accordingly. If the horns of the new moon are perpendicular, they say we are to have a wet moon, and at haying and harvest time, many a good crop is saved by the prompt advantage taken of every clear day; because, they say, we shall have very few such days this moon. This, to be sure, is a very useful error; but its opposite more than balances the account. When the new moon shows her horns in a horizontal position, somewhat like a section of a bowl slightly inclined upon its side, then they say we shall have a dry moon, and the hay and the crops are neglected, because "we shall have plenty of dry weather this moon." Now there is no "old saw" more useful to farmers, than the good old adage—"make hay while the sun shines;" which means, do whatever you have to do, and can do, to to-day, and let the moon mind her own business, as you may be sure she is inclined to, if you will only let her alone—she cares no more for your potatoes and pork, and exercises no more influence over your operations "than the man in the moon."

On this subject M. Arago, of Paris, has written a most excellent treatise, an abstract from which we publish in the present number of the American Farmer, copied from the Foreign Quarterly Review. We request our readers to give the article a careful perusal, after which, if they have anything to do, over which they formerly supposed the moon exercised an influence, they may safely trust their own judgment in deciding whether they shall wait any longer for the "right time of the moon."

AGRICULTURAL SCHOOL.—Can any body inform us where there is an agricultural school? If a detailed description of the school, with its terms, &c. be added, the obligation of the inquirer, would be enhanced. Address the publisher of this paper.

TALLAVERA WHEAT.

MR. SMITH: *Linganore, July, 1833.*

Dear Sir,—Through the medium of your excellent Farmer, I deem it advantageous to your numerous patrons, and to the agricultural community, to offer for sale a quantity of seed wheat, known to us as the "Tallavera white wheat," which was first introduced into our county about twelve years ago as an "imported spring wheat," and as such failed; but fortunately a small quantity of which was reserved for fall sowing, by the very respectable gentleman, a practical farmer, from whom I obtained the seed, and which has since succeeded admirably, and from which by a distribution among our neighbors, large crops have been raised, and can be highly recommended for its desirable properties, which other wheats which we do grow, do not possess; that it should be sown

about ten days earlier, and it ripens about one week later than the ordinary red wheat, by which the great press of seeding and of harvest is obviated; that for several years, when sown alongside of other wheats, particularly the blue-stem, which were nearly destroyed by the *Hessian fly*, while this wheat remained untouched; that it can endure the most severe winters, and not inclined to fall or lodge, owing to its firm and strong stock of straw, which is uncommonly long; that it is a very heavy wheat, weighing last year sixty-six pounds to the bushel, (Baltimore stamp,) and for which our millers gave ten cents per bushel of sixty pounds, above the price of merchantable red wheat.

From the character of its general growth it resembles very much, the old "Lawler" white wheat. About five hundred bushels of this wheat I have nicely and specially prepared for seed, having no *garlie*, nor other impurities. I send you the accompanying sample which you will please exhibit to all the applicants, as I shall advertise that quantity for sale in the American daily paper, in which you will perceive, that I refer them to your office and paper for information.

I intend to deliver the wheat about the first of September, to Jacob Cronise, agent of the Monrovia depot of the Baltimore and Ohio Rail-road company, where persons desirous to procure the seed are requested to apply early, and where they can conveniently be supplied, or by application to

ANTHONY KIMMEL.

Near New Market, Frederick Co. Md.

LARGE MUSTARD.

MR. SMITH: *Hindes Co. Miss. June 28, 1833.*

A neighbor of mine has a stalk of mustard that measures 14 feet 3½ inches in height, one limb of it measures 8 feet 10 inches; you may rely on the accuracy of the measurement. The stalk was growing when measured. The seed is supposed to have come with beans or some other seed of that kind—at all events, it is an accidental growth. The seeds will be saved; I am promised a part, of which you shall receive a portion.

GOOD PRICES FOR TOBACCO.—A hoghead of tobacco, made by Mr. Wm. P. Thomas, of Pittsylvania, (the gentleman who got \$16 for a damaged hhd. some weeks ago.) was sold this week, at Lynch's warehouse for \$13 50. Another hoghead, made by Nathaniel P. Thomas, of the same county, was also sold at the same warehouse this week, for \$15 25.

[Lynchburg Virginian.]

LAST WINTER IN EUROPE.—Some singular facts are connected with the winter which is passing over our heads. As little of severe weather has been felt in this country as under more northern skies. The merry note of the lark was heard in Denmark in the beginning of last month; nor has there been any cold of moment in the north of Russia. At St. Petersburg the thermometer never stood so low as 18½ but for a single day, and the whole season has hitherto proved unusually mild. The centre of Europe has experienced but little cold weather, and still less snow; even in Prussia scarce a flake has been seen. The south exhibits a signal contrast; and the midland of Asia seems to have been the rallying point of cold. Turkey in Europe, too, has been afflicted with its worst extremities; at Odessa it has prevailed without intermission; and the *Ottoman Monitor* tells us that its severity in Turkey in Asia, has been such as to have greatly contributed to the suspension of military operations. In Persia, and the southern provinces of the Russian empire, it is said to have been altogether unprecedented in its virulence. Such a thing as winter is known by name only in Tiflis and Erivan, where the roses bloom in the month of January; but this year the cold has been intenser than is ever felt even in the north of Europe.—*English paper.*

CULTURE AND MANUFACTURE OF TEA.—An American gentleman, physician in this city, gives an account of the culture of tea in the Royal Botanic Garden of Brazil. Of the horticulture generally of that country, he says, "it would be as easy to furnish you with a sketch of the notions upon political economy entertained by the Patagonians, or an elaborate essay upon the state of the fine arts among the Hottentots."

The tea plant (*Thea viridis*) occupies a space, in the garden of 8 or 10 acres, is planted at the distance of four feet from each other. It is a handsome shrub, about two feet high. The leaves are stripped several times in the year; and hence arise the different sorts of tea in use. No particular care is taken of the plant. It blossoms in July, August, and September. The gathered leaves are exposed to the air for a few hours, until they begin to wilt, and are then thrown into circular pans in brick work, under which is a moderate fire. These pans are of iron, four feet in diameter, and about a foot deep. The leaves are stirred briskly for about ten minutes when they are thrown out to another person, who holds before him a flat wicker or willow frame about two feet wide and four feet in length, slightly inclined towards the floor. He strews the leaves upon this frame, and lays over it another frame of the same dimensions and materials. By moving the frame rapidly to and fro for several minutes, the leaves are curled up and fall at the lower end of the frame into baskets. The curled leaves are put over a strong fire for a few minutes, to drive out the remainder of the moisture, and are then put into chests or boxes. The writer thinks each plant would produce full three pounds annually. It is propagated by slips. The writer thinks it might be cultivated in the United States, with much more profit than is obtained from either sugar or cotton—that six men might cure and prepare for market the crop of one hundred acres—and that women and children could do a great portion of the labor. From the known similarity of the climate and soil of China to those of the United States, he concludes that it could be cultivated in the southern States, and from the fact that it grows well in Japan, as high as the 45th degree of latitude, he has no doubt that it will bear considerable frosts. We are inclined to agree with the writer, from the fact that so many of the flowering plants of China and Japan stand our winters perfectly well.—Let the people of the south patronize the exertions of Dr. Perrine, and they will soon cease to complain of the operations of the tariff.—*N. Y. Farmer.*

THE GREY OXEN OF ITALY, says N. P. Willis, in a late letter from that country, are quite a different race from ours, much lighter and quicker, and in a small vehicle they will trot off five or six miles in the hour as freely as the horse. They are exceedingly beautiful. The hide is very fine, of a soft squirrel grey, and as sleek and polished often as that of a well groomed courser. With their large, bright, intelligent eyes, high lifted heads and open nostrils, they are among the finest looking animals in the world when in motion.

FOREIGN MARKETS.

LONDON, June 16.

Cotton.—The cotton trade continues very brisk; the demand for the raw article and for manufactured goods most extensive. The purchases of cotton in this market last week, by private contract and public sale, were above 7000 bags; a further improvement of 1-3d per lb. was realized, a great proportion of the cotton was taken on speculation.

LIVERPOOL, June 25.

The cotton market has been very brisk throughout the last ten days and the sales on an extensive scale, being about 45,000 bags, of which 12,000 have been taken by speculators. Prices of Sea Islands are 4 a ½ advance, and other sorts of American are about 1-8d higher.

AGRICULTURE.

(From the New York Farmer.
MANAGEMENT OF A DUNGHILL.By ROBERT SOMERVILLE, Esq.
Of Huddinton, Scotland.

A friend has put into our hands the following essay on the important subject of collecting and manufacturing manure. It will be perceived that the plan of having the manure in hollows, recommended by distinguished agriculturists, among whom is J. Buell, Esq. is not approved. We are fully of the opinion, that manure remaining for any considerable time trodden down in excess of wet, is very destructive to its nutritious properties.—*Ed. New York Farmer.*

The dung of quadrupeds is the most common, the most useful, though not perhaps the best managed, of any manure that is at present grown. Previously to entering upon the way of using it, we trust a few observations upon the present defective mode of treating it, together with some account of its properties, the means of collecting, preserving, and subjecting it to the process of fermentation, and of increasing its quantity, will be thought of service.

Mode of management at present.—When any considerable quantity, either of stable dung or mixture of animal and vegetable substances, is collected together under certain circumstances of heat, air and moisture, they begin to ferment, and exhibit all the different phenomena of fermentation in a great or less degree, till the process is finished. If we then examine the mass, we find that the vegetables, of which it was originally composed, are decomposed and reduced to their first principles, and are again in a situation to afford food for new plants; by this means a perpetual succession is kept up, and the decay or death of any of these, which, at first view, we might be lead to consider a misfortune, serves for their reproduction.

This point settled, it will readily be admitted, that the more completely such substances are subjected to the process of fermentation, the greater and more beneficial their effects will be upon the soil. It is, therefore, an object of the first importance with every person concerned in the cultivation of the earth, to manage their manures in such a way that they might be completely fermented; and to have their dunghills so situated and constructed as to promote fermentation, and preserve the useful particles contained in the dung, both while the process was going on, and after it is finished.

A careful attention to these points will not only improve the quality, but, as we shall afterwards see, increase the quantity of manure in an astonishing degree.

When fermentation has taken place for some time, in a heap of manure consisting either of animal or vegetable substances, or a mixture of both, the first alteration that is observed is a change of color, and a sensible diminution of its bulk: as the process advances, the bulk continues to diminish, till the fermentation entirely ceases. The diminution is owing to the solid parts of the mass being brought more closely together. The fixed air and volatile alkali escape in form of vapor, and the moisture falls to the bottom, where it either remains, if the dunghill is situated in a hollow, and has a bottom capable of retaining moisture, or runs off, if it is situated upon a declivity.—When this moisture is collected and carefully analyzed, it is found impregnated with the salts contained in the dung, and if spread upon the soil in that state, it will contribute to fertilize the land.

In collecting and preparing dung in this manner, little attention has hitherto been paid either to the site of the dunghill, the encouragement of fermentation, or the preservation of the salts after the fermentation is finished; accordingly we observe the greatest part of dunghills either situated in hollows, and surrounded

with water, which, by chilling the mass, very effectually prevents fermentation—or upon declivities, where they are totally exhausted of every drop of moisture. In these cases, the dung is thrown out carelessly: horses, cattle, hogs, and poultry, are allowed to trample upon and spread it, and even carts and wagons are driven over it.

By this treatment it is pressed into a mass too heavy and compact for the air to penetrate through a great part of it; the sides of the dunghill are scattered about, loses its moisture, and is either blown away by the winds, or returns to a state little better than dry straw; and, when the season arrives for laying it upon the land, the whole is taken out, without considering whether it has fermented or not.

Defects of this management.—To a person who has paid any attention to the subject, the defects of this management must appear in a very striking point of view. The middle of such a dunghill from being hard pressed will be long in fermenting, and even in the end be very imperfectly fermented; and the sides, from being so scattered about and dried, will not be fermented at all. We need hardly observe that the consequences of this management will be a scanty crop, and disappointment to the farmer: this is the ordinary effect, where dung is laid even upon a plain surface.

Bad effects of Dunghills being placed in a Hollow. When the dunghill is situated in a hollow, and has a bottom capable of retaining moisture, the consequences are equally bad, if not worse. The whole of the rain that falls immediately from the clouds, together with the water from the roofs of the surrounding houses, and the natural moisture of the dunghill itself, lodge there and chill it, so as to prevent fermentation. It is certain that stable dungs in such situations will have the appearance of being fermented, but upon examination it will be found only decayed, and from its being steeped so long in water, the greatest part of the salts will be extracted, and what remains, if carefully analyzed, will be found to contain scarce any other principle but vegetable earth.

Loss attending Dunghills being situated upon a declivity, or gravelly bottom.—Where a dunghill is situated upon a declivity, or has a gravelly bottom, the loss is equally great as in the former cases, as the whole of the natural moisture that is pressed out during fermentation, and which is strongly impregnated with the salts of the dung, either runs off or sinks into the earth; nor is this the only loss that is sustained—every shower that falls, by passing through the mass, carries off an additional quantity of the salts, till by repeated washings, the dunghill is left in nearly the same situation as tea-leaves, after a strong infusion has been drawn from them. Finally, by throwing it out in the careless manner already described, taking no pains to lay it up regularly, and allowing cattle, &c. to tread upon, and carts to pass over it, fermentation is long in taking place; even then it is partial and incomplete, and in place of producing good manure, abounding with rich, well prepared substances, it will for the most part be found to consist of articles only half fermented, which, from their parts not being properly separated, are very ill calculated to promote vegetation. Dung is the most likely to be best where the dunghill is upon level ground, and at some distance from the offices.

Having mentioned the present mode of collecting and preparing stable dung, and stated the slothful and defective manner in which it is generally done, we shall now proceed to offer some directions as to the methods of promoting fermentation, and preserving the salts after the process is finished; and lastly, of increasing the quantity of that valuable article.

To promote fermentation in stable dung.—To promote fermentation in stable dung, two things are essentially necessary, namely, air and moisture: without these, no fermentation will take place; and unless they are in due proportion, the process will be incomplete.

It is a circumstance well known to persons who are accustomed to prepare dung for hot beds, that by laying it lightly together in heaps, and watering it gently, fermentation is immediately brought on. It is also known, that in the after stages of this business, hot-bed dung is as completely fermented in the space of fourteen or sixteen days as that in a farmyard generally is in six or eight months.

Every farmer ought, therefore, to institute this practice as nearly as the nature of his situation will admit; and in place of having his dunghill in the stable-yard, allowing carts, cattle, hogs, poultry, &c. to trample upon and disturb it, he should place it in some distinct situation, convenient for his offices, the urine from which should run into receptacles, from which it might be thrown; without the trouble of carriage, into the dung, where it would be of the utmost use in promoting fermentation.

When it is driven to the dunghill, the cart or wagon in which it is carried, should not be driven over the dung as is commonly practised; because as we formerly observed, the feet of the horses and the weight of the carriage will press it so hard, that the air will be in a great measure excluded, and by that means fermentation prevented.

If we inquire either of the farmer or his servant what is gained by this exertion, he will only be able to say that the load is laid upon the top of the heap—a labor which a man could readily perform to much better purpose in a few minutes: the whole cart load ought to be laid down by the side of the dunghill, and afterwards thrown lightly upon it with a fork—the trouble of doing which would be trifling, and the advantage immense.

If dung laid up in this way contains a sufficient proportion of moisture, it will immediately begin to ferment, and the process will be soon and completely finished. Particular attention ought therefore to be paid to this circumstance; and if at any time the dung is laid up dry, it should be immediately watered. In summer this will frequently be found necessary, especially during dry weather; and as most farms possess a sufficient command of water, it can very easily be done.

Where this method is had recourse to, the dung will be completely fermented in the space of six or seven weeks at the utmost, and in general will be found of one-half more value than that which is made in the careless and slovenly manner we have described.

Situation and construction of Dunghills.—The importance of good manures to all agricultural operations is such, that we should naturally have expected to find every thing relating to it made a primary object with farmers. On the contrary, no part of rural economy has been less the subject of inquiry: the situation and construction of dunghills in particular, though highly deserving of notice, have for the most part been considered as a matter of indifference.

As was formerly mentioned, a hollow is improper for the site of a dunghill, from the circumstance of its lodging water, and preventing fermentation: a declivity is equally bad, as it serves to drain and carry off the moisture saturated with the richest salts of the dung; a gravelly bottom is worse than either of those, as the moisture sinks down into the earth, and is irrecoverably lost.

Proper situation for a Dunghill.—The situation best calculated for the site of a dunghill, is that which is nearest to a level, with a bottom capable of retaining moisture, and, if possible, covered with a shade. The whole should be enclosed with a wall at least four or five feet in height, with an open space at one end for carting away the dung. If the bottom is not clay, it should be laid with, and paved above, either with broad flags or the common paving stones used for streets. The American farmer may find it convenient to lay a floor of thick plank. At the end opposite where the opening is left, a reservoir should be dug, which might either be lined with clay, and built round with stone, or fitted with a wooden cistern

made water tight, into which a pump should be put for drawing off the moisture daily.

This reservoir should be situated at the most depending part of the dunghill, with an opening in the wall immediately opposite to it. The pavement should have a number of channels of a least five or six inches deep, and the same in width, all tending towards the opening; these channels should be well paved, and filled with brushwood before the dung is laid down; by which means they will be kept open, and the moisture find a ready passage to the reservoir. For better explaining the idea, we refer the reader to the annexed plan of a dunghill, with the proposed channel and reservoir. Every dunghill should be so situated as to have its longest sides run from east to west, surrounded by a wall, and covered with a roof. The wall on the south side of the dunghill should be of such a height, as to prevent entirely the sun's rays from touching the dung on the other three sides, however, there is no necessity for its being so high; six feet from the ground will be quite sufficient, and the roof can be supported by pillars.

The expenses of a roof, which need only be thatched, will soon be compensated, not only by the superior quality of the dung, but by the conveniences which it will afford, as it may easily be converted either into a pigeon house, a poultry house, or a store for the smaller husbandry utensils.

(From the Genesee Farmer.)

ON THE CULTURE OF LUCERNE.

We are gratified in being able to give the following interesting communication on the culture of lucerne, from an English gentleman who has recently emigrated to Canada; and we hope the writer will often employ his pen for the benefit of the farmer.

Caraboe, Upper Canada, May 12, 1833.

This plant is much, though not generally, cultivated in the south of England, and its excellence so fully proved by those who have taken the pains to adopt the proper mode of culture, that I do not hesitate furnishing you with the plan I for many years pursued, that your readers may follow it if they think fit so to do, how I shall get on in this country on new land, and among the stumps, time must show—but having fully ascertained the intrinsic worth of the article, and the profit of it to a farmer, I mean, as far as circumstances will permit, to adopt my English plan of culture. I do not hesitate strongly to recommend its growth to my neighbors and your friends the patrons of the Genesee Farmer, as experience has convinced me it is both the most productive and nutritious green food, that can be given to any animal.

The first thing that requires attention in the cultivation of lucerne is the quality of the soil, which must not be wet at bottom. A bottom of loam, sand, gravel or stone, and not of clay, as that always more or less holds water, and when the roots of the lucerne come to the stagnant water the plant begins to perish. I have always sown in March, but in this country I should say from the middle of April to the end of May, is the most proper and best season.—Two modes may be pursued—the first I shall adopt here and recommend to all similarly circumstanced with myself, on new land and while the stumps are standing, as it will I think be most convenient, but on clear ground I should prefer the second mode.

Prepare a small seed bed by letting it be well cleaned and dug deep; (for the tap root of lucerne runs to a great depth;) sow the seed very thinly in rows about eighteen inches apart; when the plant is well up take care to weed and keep your rows clean, for grass and weeds are the destruction of lucerne. The grand secret (if such it may be termed) in the culture of lucerne, from beginning to end, is **KEEP IT CLEAN**. My Canadian brethren say, that is too much trouble, and will be too expensive in the present state of things, while labor is at the present price; but I

tell them all, it will repay, and that handsomely, to attend to the cultivation of lucerne and therefore I wish to see it well done. Sow as thin as you can; the plants will come too thick. In the ensuing spring I shall proceed with my next step, though it may be as well to wait over year or till the fall. Clean and plough deep your land—drag it as smooth as possible—prepare drills two feet apart, transplant some of your strongest and most healthy plants into these drills at least one foot asunder, for when a few years old a vigorous plant of lucerne will occupy at least a circle of a foot square. By this means you can the more readily (and which must be done) plough every spring between the drills and hoe the sides of the plant. I thus thin my seed bed, and the remaining plants will gain strength and thrive the better. The following spring I shall clean my seed bed by transplanting, and follow up my drill system. You must cut off the grass from your plants late in the fall, before it begins to die away. The first year after transplanting it should only be cut once, but in succeeding years you will I doubt not be able in this climate to cut it at least four times.

In England, I one season cut six times, and at four of the cuttings the produce was, I am sure, not less than at the rate of from six to seven tons to the acre, at each cutting; but than I hoed it between each cutting; manured well in the autumn, which was dug in early in the spring before the plant began to shoot.—In short, I made it a hobby and entirely adopted garden culture, but that will be expecting too much from a Canadian farmer; however I was repaid for all my trouble and expense.

The second plan is simply to sow your seed in drills and at the distances I before named; keep trimming out your plants from time to time so that no two plants touch—for I am persuaded that two good healthy plants standing separate will produce as much as five that touch or are huddled together.

Thus cultivated, and **KEPT CLEAN**, with a little rotten manure, put on in the fall after your last cutting, and ploughed in the spring, lucerne will stand and prove a flourishing and profitable crop from twenty to twenty-five years.

Lucerne may be and is also sown broadcast, proving a most profitable crop for a few years; but as it cannot endure grass or weeds on the surface, I should not think of sowing it thus to stand more than three years; and I deem it, sown in this way, a better and more profitable crop than sainfoin which is only a triennial.

I should add, the fly will as greedily devour the young plants of lucerne as they do the turnip, but that is of little consequence, if you adopt the plan of transplanting or drill system, and then thin from time to time.

I threw down a small quantity of seed last year as late as September, it came up, took good root and has stood the winter of this climate to my entire satisfaction.

J. VENIS.

(From the New England Farmer.)

PREPARATION OF SEED CORN AND WHEAT.

MR. FESSENDEN: Deerfield, June 17, 1833.

In addition to the information you have given on preparing seed corn with tar, I cheerfully comply with the request of your "worthy friend, Essex North," in relation to that subject. My method of preparing seed corn with tar, may be unlike that of any other person; whether it is as good or better, I am unable to say; I only know it answers my purpose perfectly well.

I put my tar into a kettle of boiling water of sufficient quantity to cover the whole of the seed I wish to prepare; when the tar has remained long enough in the water to become a thin liquid, I turn my corn into the kettle or other vessel containing the hot water and tar. I then turn off the water, leaving the corn and the tar at the bottom, and commence stirring it while hot,

and continue it till the tar is equally distributed among the corn, and every kernel has received a wetting; I then sprinkle in plaster, and continue sprinkling and stirring alternately, until the tar is all absorbed and the kernels completely separated and dry.

I have never used any thing to make the tar thinner, nor have I ever soaked the corn previous to the preparation; though I am not certain but it would vegetate sooner. Yet I think that if the tar *should* be an obstruction, that the swelling of the seed, after the application of tar, would assist the germ in bursting the envelope with which it is enclosed. I mention one fact, however, to show that tar alone is no obstacle; in the course of my planting the present season I got out of tar, but had on hand a mixture of tar and rosin, so hard that it would scarcely yield to pressure; I used this as a substitute with equally good success. I am not very particular as to the quantity of tar, not measuring it, but should think rather over half a pint to one peck of corn.

Winter grain looks well, as is usual in cold seasons, and this so far is certainly one.

A new era has commenced here in the culture of winter wheat, on old lands. If the ground be well prepared and in a high state of cultivation, as much certainly attends this, as most other crops; a top dressing of manure, to be harrowed in with the seed answers well. Lime should also be freely used. Wheat on strong lands should be sowed thick, from two to two and a half bushels to the acre, is not too much; this makes the straw fine, is much less liable to rust and blight, or to lodge down flat, and rot, than when sowed thin.

My method of preparing seed, is to put it into brine fully saturated with salt; this is a little too strong; as it will float too much of the wheat, dilute it a little with water, so that the plump wheat will go down, leaving all the foul seed, lighter than wheat, on the surface, to be skimmed off, then drain the brine from the seed and stir in slaked lime with the wheat.

Yours, respectfully, J. WILSON.

(From the New York Farmer.)

BONE MANURE FOR CORN.

In conversation with Dr. B. of Long Island, we learn that his application of bone manure is attended with beneficial effects on corn. The bone was first fermented by heaping it up with a sufficient quantity of horse manure, to produce fermentation, and then spread on the ground at the rate of twenty bushels to the acre. Although the season is very backward for corn, yet now, 25th June, the contrast with other portions of the field manured in various ways is quite considerable.

His farm is about eight miles from the landing.—The expense of carting a load of twenty bushels of bone dust is seventy-five cents. This added to the cost of the bone, at the rate of thirty cents a bushel, amounts to six dollars and seventy-five cents. A moderate manuring of leached ashes, the most favorite manure of Long Island, requires five loads, costing one dollar and seventy-five cents; this together with the cartage amounts to twelve dollars and fifty cents, showing a difference of five dollars and seventy-five cents in favor of bone manure. By reference to former pages of the current volume of the New York Farmer, it will be perceived that this manure is of a durable nature; and the advantages of using it cannot fail of being perceived, especially by those farmers who are obliged to cart their manure a considerable distance. We shall continue to make our readers acquainted with the results of experiments now making with this most important manure, and in the mean time we hope they will not be backward in adding to the stock of information by trying similar experiments. It is with pleasure we learn that several of the neighbors of Dr. B. intend giving orders for considerable quantities for fall crops.

HORTICULTURE.

(From the Genesee Farmer.)

GERMINATION OF SEEDS.

Greatfield, 7 mo. 6, 1853.

It is often said of certain seedsmen that they are in the practice of selling *bad seeds*; that is, either seeds that have been kept too long to vegetate, or seeds in which the vital principle has been purposely destroyed by *baking*. The supposed design is to increase the sale, so that when the cultivator has sowed one paper, he may be induced by its failure to purchase another.

To these charges, I make no reply, except that I am satisfied *good seeds often fail to grow*.

I sowed some of the scarlet Havana tobacco, from which I had not a single plant. This proof of its being bad was about as strong as people commonly have, when they condemn a parcel. The next year however, I sowed some from the same parcel of seeds when they were *one year older*, and had as many plants as I wanted.

Laterly when I obtain rare seeds not known to grow freely, I sow them in as many different situations as are likely to prove favorable. Some seeds will grow in almost any part of the garden; but others are brought to germinate with difficulty; and it is not uncommon to have them growing in one spot when they entirely fail in every other. Of this I have several instances in the present season. The failure of rare seeds to grow in common gardens, I should scarcely consider as any proof that the seeds were bad.

To understand this subject we must remember that seeds of this sort are generally from climates very different from our own; and to a different temperature, and a different degree of moisture, we often add a difference of soil. The seeds of our wild plants are sown by nature in vegetable earth, and in the shade. Many of them refuse to germinate in cultivated land. Who would think of raising from seed the *Orchis*, or the *Cypripedium*, in a common garden? Or even *Gerardia flava* or *Gerardia glauca* which are sure to dwindle and perish in the open sunshine?

Many seeds are very small, as those of *Mimulus*. If these have much more than a sprinkling of fine earth over them, they are irretrievably lost. They must be left then, near the surface. But if this be allowed to dry, they cannot grow. If they sprout during wet or cloudy weather, the first hot sunshine may dry the earth deeper than their *very short roots* penetrate; or its heat may destroy them. These plants, from their small size and brief duration, may not be observed; and the seeds from which they have sprung will of course be condemned.

I must here make a digression. Very small seeds, after being slightly covered with vegetable earth on the north side of a fence or wall, may be further protected with fine brush,—particularly with the leafless branches of hemlock. I have used it with great advantage. While it admits light enough, it intercepts the direct rays of the sun, and prevents the wind from drying the surface of the ground. As the plants acquire strength, a part of the brush may be removed from time to time.

Seedling plants are sometimes not found so soon by the sower as by insects. I lately sowed *Petunia nyctaginifolia* in two places: in one spot the plants grew well; in the other they were totally destroyed by insects soon after they came up; and had I examined the spot one day later, I should probably have concluded that the seeds had not germinated.

In garden beds where seeds have been evenly sown, the young plants often appear in distant patches leaving wide spaces unoccupied. This is no proof that the seeds were bad. Either insects have destroyed the plants that grew immediately, or some parts of the ground have been more favorable to the ger-

mination of the seed, than other parts, and the latter suggestion is by no means improbable. Even in hot beds, where insects intrude more seldom, we may often observe one part of a short row crowded with plants, while in another part, only a few inches distant, not a plant can be found.

The seeds of some plants germinate very sparingly as *Nuttallia pedata*. By no treatment which I have yet given them, has more than one plant been produced among thirty or forty seeds.

It is doubtful if seeds of *Dictamnus* can be made to grow after they once become dry. I have never succeeded with them after they had been kept a few weeks in the house.

Some seeds seem to be more perfect in certain years. I have had to increase the white *Polemonium caeruleum* by division; but in the present season, I have many hundreds of young plants from seeds naturally scattered.

I therefore conclude that seedsmen ought not to be so charged, unless the proof be more direct than a simple failure of rare seeds under common culture.

D. T.

[The Editor of the American Farmer takes the liberty of adding to the above the remark, that many seeds lay in the ground a year before they vegetate, and many others must be sown immediately after they are gathered, and then remain till the next spring in the ground. Those who would have good marigolds, poppies, *Clarkia pulchellas*, and many others, must sow the seeds in the fall, as also should be sown all our native flower seeds.]

(From the London Gardener's Magazine.)

A SUCCESSFUL METHOD OF CULTIVATING THE CHRYSANTHEMUM INDICUM.

Courtlands, Jan. 18, 1828.

Sir,—The following method of treating the chrysanthemum, is, I believe, new; and as it answers successfully, I think it may be acceptable to some of your readers.

In the plan of cultivation to be described, I propose to myself to obtain all the advantages of different heights, large flowers, and the best disposition of the whole plant during its flowering season.

To procure the highest growth, I detach from the old plants the most promising suckers, about the first of March. These I place singly in small pots, and set them in a cold frame, giving the usual attention, and shifting them three times in the course of the summer.

My second are set from cuttings struck about the middle of May, placed singly in pots, and are shifted twice in the season.

The lowest grade, which form bushy plants, rise from eight to eighteen inches high. To obtain such, I do not keep them down by pruning, as is commonly done, but by layering some of the principal shoots in the following way:—Having some of each variety planted in the spring, on a south border, there they are allowed to remain till the middle of August, at which time they have formed fine bushy heads, and from these are to be produced my dwarf-sized plants. Previously to layering them, I select and bend down to the surface of the ground as many as are wanted, fixing them there by long hooks, at the place whence I propose the new roots shall proceed. In a few days the shoots regain their natural upright position, they may then be layered in pots placed close thereto, and half-plunged in the soil; this is easily done without risk of breaking off the points, to which they are liable by a different practice. When placed in the pots, fix them there by hooks, which should be long enough to pass through the hole at bottom, and thus keep the whole steady. The layers are assisted by regular watering, and having moss or short grass laid on the surface of each pot: when sufficiently rooted, they are taken off, and shifted into larger pots, in which they are intended to flower.

My next object with all these sets of plants, is to

train them to the best form: as stage-flowers, they should present their best face to the spectator, every flower should be seen, and they should be regularly arrayed as possible. To train them to this effect, I place them, as soon as shifted for the last time, against a south wall, allowing them plenty of room from each other, plunging the pots in the ground, and fixing the principal shoot only with a shred to the wall. In this situation, they in a short time acquire the desired form, which they retain throughout the flowering season. The plants are not tied to sticks till the flower buds begin to form; they are then detached from the wall, but still kept as near it as possible. To give the necessary symmetry, a little contrivance must be resorted to; some of the longest side branches which are not wanted, or may be spared from the top, are bent spirally downwards behind, and their points protruded through the foliage below, so that flowers may appear regularly over the face of the plant. I use small copper wire for this purpose, which I find much more suitable than either brass or thread.

Large flowers are obtained by a judicious thinning of the flower buds. Those sorts which have many secondary buds should be divested of them, especially if they are inferior in size and untimely in blowing. From one to three of the most promising will suffice for every side branch; and in most cases one only may be enough, provided the buds are properly distributed. This thinning ought particularly to be practised on the superb white, two colored red, changeable pale buff, &c. but such as are cluster flowers should be thinned more sparingly; the superb cluster yellow, for instance, which flowers in a kind of raceme, should be allowed to show its character.

I am, sir, &c.

WM. MITCHINSON.

(From the Genesee Farmer.)

SUN FLOWERS.

Buffalo Horticultural Garden, }
May, 1853.

MESSRS. EDITORS:

In a late number of the Farmer, *Ulmus*, one of your most interesting and valuable correspondents, puts down the sun flower as utterly useless, excepting as a flower. I have no great opinion of it myself for very profitable crops, and agree with him that it is a splendid appendage to the flowering department of the garden. I admire the stately growth of the plant as well as the flower lifting its tall head far above its more humble contemporaries, always watching the sun to catch his first and last beams. The seeds, however, I consider valuable for feeding poultry, but not to be preferred to corn, which they always choose before any thing else. The plant may be made to produce an abundance of seeds with but very little care or trouble. The seeds should be put in the ground as early in spring as possible, and if convenient to plant them in the fall it is all the better. It requires a middling rich soil—if very rich it runs too much to stalk, and if very poor produces but little seed. As soon as the first flower appears, it throws out a great number of branches from its sides, each of which will if let alone produce a flower, which if permitted to remain on the stalk, the seed cannot all ripen; these should therefore be removed, leaving only from four to six heads which will be well filled with good heavy seeds; but one plant should be suffered to grow in a place—plant four or five feet apart. I fed the seeds to forty or fifty fowls once or twice a week all last winter as a change of food, and they appeared to be as fond of them as of corn. And besides their grand appearance when in flower, and remaining so, as they do, for a long time, they invite into the garden, and about our houses great numbers of yellow birds, attracting them away from our more valuable seeds, and bringing the sweetest of music to our windows and our ears, cheering us amidst our labors; and besides all this, they furnish food for chickens, preparing them to cook well for thanksgiving and Christmas dinners, and affording us eggs for pumpkin pies in the fall.—

Now, duly estimating all these advantages, who would give up and condemn the sun flower?

Another of your correspondents apologizes for Ulmus by recommending a better and larger than the common sort, and says that his produces flowers three feet in circumference. This is *prodigious* large though—I should like well to obtain some of the seeds. I think this kind must have originated on the island where the pumpkins are said to grow so large that they are used for sentry boxes.

A. BRYANT.

RURAL ECONOMY.

ESSAY ON COOKING FOOD FOR HORSES.

BY MR. DIX, VETERINARY SURGEON.

The following extract cannot fail to be highly interesting and useful to the owners and managers of horses.

Horses, like other animals, do not always content themselves with just eating what is necessary for their proper support: they are apt to indulge in any thing they find agreeable to their palate; and there is an immense variety in their food, if we look to the various grasses which are to be found in good old pasture, and by that indulgence they expose themselves to various diseases, and, for the time, render themselves unfit for any active exertion. If a horse's bowels are loaded with clover, or any kind of food, we know he could not gallop any great distance without injuring himself. If he has been fully fed, and is allowed to drink freely of water, and afterwards started on a journey at a smart pace, the almost invariable consequence is, that he begins to purge, he is soon fatigued, he perspires from the weight he is carrying in his belly, he gets sick, and cannot go on. The natural action of the bowels throws off the load, and if the horse is not pushed on too fast, he is sometimes able to get well to the end of his journey; but if his pace is increased he gets sick, the load and mass contained in the stomach and anterior portion of the bowels cannot escape, and as exercise prevents and suspends the digestive process a chemical process is set up in its stead, producing rapidly various derangements, which are too frequently followed by violent disease or death. This occurs less frequently in well regulated coaching stables where a regular and large allowance of oats are given; because, as in coaching stables, the quantity of oats is so large that little hay is eaten, the horses are therefore less liable to gorge themselves than under other circumstances, but even there, it is generally, nay, I may say invariably, considered necessary to turn the horses round in their stables for half an hour before starting, in order that the stomach may have time to act in some degree upon what has been taken into it, and that it may have passed into the bowels. The animals, are, by this means, allowed time to empty themselves, which they will generally be found to do as they leave the stable or as they start with the coach.

Under this view of the subject, it will be seen that a moderate proportion of nutritious food is only required, and that it is advisable to present it in as small a compass as will suit the nature of the digestive organs. But it would appear that a certain proportion of bulk is also necessary to the quantity of nutritious matter, to keep up the proper action of the bowels. If the food is too rich and too much concentrated, it deranges the stomach and bowels and produces disease; if too poor and bulky, it yields not the proper degree of support to the animal, while its bulk impedes respiration, and its weight detracts, by its burdensomeness, from the capability of the animal exerting himself.

From these remarks, it will appear obvious, that the grand desideratum is to give food containing as much nutriment, and in as small a bulk, as is consistent with the economy of the animal.

If this problem is solved, it will follow as a co-

rollary, that it will be important to give that food which has been found best suited in its proportions, in such a state as is best suited for digestion. This is a point however, worthy of consideration, and naturally suggests the question, how is the body supplied with nourishment by taking in food into the stomach? The common notion is, that much depends, as I have indeed before mentioned, on the hardness of the food; and it is a common saying, in order to show off a horse which is in condition, "that he has plenty of hard meat in him." Now, this is a very silly and erroneous idea, if we inquire into it, for whatever may be the consistency of the food which is taken into the stomach, it must before the body can possibly derive any substantial support or benefit from it, be converted into chyme,—a pultraceous mass; and this as it passes onward from the stomach into the intestinal canal, is rendered still more fluid, by the admixture of the secretions from the stomach, the liver, and the pancreas, when it becomes of a milky appearance, and is called chyle. It is then taken into the system of the lacteals, and in this fluid, this soft state—and in this state only—mixes with the blood, and passes through the circulating vessels for the nourishment of the system.

The food, no doubt, when taken in the stomach, at once satisfies the animal's hunger; but if the digestion is suspended by any means, it soon proves injurious, and weakens, instead of supporting, the system.

Now, if the hardest of the food must, in this manner, be broken down and dissolved before it can really enter into the system, it must appear evident, that something approaching to this solution, if done artificially, would greatly aid the organs of digestion in this process, and that thereby much exertion might be saved to the system, and, at the same time nourishment would be more rapidly conveyed into it. It is with this view that I would recommend the general adoption of cooking food for horses and cattle.

When the food is broken down by cutting the hay and straw, and bruising, boiling or straining the oats, not only is there less waste, by the whole being used as manger meat, but much labor is saved to the animal, in having tough dried hay, and hard oats, masticated for him, and in a state almost prepared for digestion; and as regards the oats, all the nourishment they can afford is readily yielded to the digestive organs; for not only may I refer to the fact already stated regarding the poultry on board the *Coldstream Indiaman*, but I may also observe the fact that we find, that unless the grain is broken down, or otherwise killed by boiling, it is not acted on, and will grow as readily after having passed through the horse, as the olives did after having passed through the turkeys. Oats like every other seed, is possessed of vitality, and it would appear that the organs of digestion, and their secretions, do not act upon bodies possessing it. Were it not for this exception, the gastric juice, which acts upon and dissolves every dead matter taken into the stomach, would act upon the stomach itself; but it is not possessed of this power. Worms are, from this cause, also allowed to live in the stomach, but when dead, become acted upon like other dead matter. Hence we often find worms when destroyed by medicine, disappear, although we have not observed them pass with the feces.

It is, therefore, necessary to destroy the life of the food taken into the stomach, before it can yield nourishment to the animal. This may be done, as already stated, by bruising; and the finer it is bruised the better, because it is capable of being more completely mixed with the cut straw or hay, and the whole is then more easily eaten; but as the experiments of Captain Cheyne have shown, it may also be steamed or boiled, and given with the same advantage, and from what has been stated regarding digestion, it must be pretty obvious that this kind of cooking brings the food nearer to the state of being readily dissolved and acted upon by the digestive organs. The only ob-

jection which will at once occur, I know is, that boiled or steamed meat will incline a horse to purge; this, however, is not so much the case as many, without trial, may suppose, and where it does occur, is perhaps owing to too large a quantity being given at one time, as indeed is almost invariably the case; for stablemen, when they give boiled food, always suppose it necessary, at least the practice is, to give nearly double the quantity or more at a time, than they would think it proper to give of raw food; but if the rich cooked or stewed food is mixed with a less nutritious and raw material, the whole of the boiled is taken into the system, without producing the laxative effect. Nay more, it sometimes proves, in cases of horses which have a natural tendency to purge, that, by a judicious use of soft feeding, this is overcome. Captain Cheyne had a grey horse of this kind, and it was feared that he would not agree with the feeding, but it is found he now does his work better than ever he did, and with less tendency to laxity of bowels than formerly, and when I saw him a few days ago, he was as fat on the rib as any horse in the working condition ought to be.

All horses on this restricted feeding are found to be light in their belly; but, while this is the case, the appearance of their coats, the quantity of fat on their ribs, and the manner they are able to do their work, show that they have sufficient nourishment, while (what is the subject of the most important consideration with me) their dispensing with the doctor shows that their health is most materially improved by it. In conclusion, I shall only at present mention, that as I was passing Mr. Croad's office, two or three days ago, and observing a pair of horses, as fresh as racers, in one of the pair horse coaches, he observed, what was worthy of notice, "There's condition for you," and (pointing to about two bushels of oats and cut hay on the coach) "this is there allowance for the night, and which is sent out regularly every day to the uut stages."

If such, then is the fact with regard to horses doing fast work, the advantages which might be obtained by a similar plan being adopted among farm horses, must be too obvious to require further argument.—*Ed. Quar. Jour. Aug. 1832.*

(From the American Sentinel.)

INCOMBUSTIBLE WASH AND STUCCO WHITEWASH.

The gentleman who furnishes the following, assures us that the receipt is what it purports to be—and that he believes it to be a very valuable one.

The basis for both is lime, which must be first slaked with hot water, in a small tub or piggin, and covered to keep in the steam; it then should be passed in a fluid form, through a fine sieve, to obtain the flour of the lime. It must be put on with a painter's brush—two coats are best for outside work.

First, to make a fluid for the roof, and other parts of wooden houses, to render them incombustible, and a coating for brick tile, stone work and rough cast, to render them impervious to the water, and give them a durable and handsome appearance. The proportions in each receipt, are five gallons. Slake your lime, as before directed, say six quarts, in which put one quart of clean rock salt, for each gallon of water, to be entirely dissolved by boiling, and skimmed clean, then add to the five gallons, one lb. of alum $\frac{1}{2}$ lb. copperas, $\frac{1}{2}$ lb. potash—the last, to be gradually added; two quarts of fine sand or hard wood ashes must also be added; any coloring matter may now be mixed, in such quantity as to give it the requisite shade. It will look better than paint, and be as lasting as slate. It must be put on hot. Old shingles must be first cleaned with a stiff broom, when this may be applied. It will stop the small leaks—prevent moss from growing—render them incombustible, and last many years.

Second. To make a brilliant *Stucco whitewash*, for all buildings inside and out. Take clean lumps of well burnt stone lime—slake the same as be-

fore, add 4 lb. whiting or burnt alum pulverized, one lb. loaf, or other sugar, three quarts rice flour made into a very thin and well boiled paste, starch, or jelly, and one lb. cleanest glue, dissolved in the same manner as cabinet makers do. This may be applied cold within doors, but warm outside. It will be more brilliant than plaster of paris, and retain its brilliancy for many years, say from fifty to one hundred.—It is superior, nothing equal. The east end of the President's House, in Washington, is washed with it.

MISCELLANEOUS.

(From the Foreign Quarterly Review.)

INFLUENCE OF THE MOON.

Annuaire pour l'An 1833, présenté au Roi par le Bureau des Longitudes. Notices Scientifiques par M. Arago. 15mo. Paris.

Among the opinions or prejudices relative to the phenomena of the natural world, which mankind seem to have adopted by common consent, there is none which has prevailed more universally, or from an earlier period of time, than that of the moon's influence on the terrestrial atmosphere and the state of the weather. It is in vain that philosophers affirm that they can trace no physical connection between the moon and the effects ascribed to her; to the sailor, the agricultural laborer, and indeed the great mass of mankind, the influence of the moon on the weather is a *fact* established by every day experience, the truth of which it would be absurd to call in question.—Whether the notions so universally diffused on this subject are to be referred to the class of vulgar prejudices, or have any foundation in fact, is a question which M. Arago has discussed at considerable length in the excellent little annual whose title we have now copied. In the present state of science such a discussion may to some appear superfluous, but the labor of the philosopher is not thrown away when it tends to eradicate even a single prejudice. For this reason and because the subject is in itself really very curious, we are induced to present our readers with a brief abstract of M. Arago's very interesting paper.

The first question which M. Arago undertakes to examine, is, *whether the moon exercises any influence on the rain.* The data on which he founds his remarks are derived from a series of observations published by M. Schubler, a professor at Tübingen. They comprehend a period of twenty-eight years, and were made at the following places, namely at Munich, from 1781 to 1783; at Stuttgart, from 1809 to 1812; and at Augsburg, from 1813 to 1828. From the comparison of these observations, it appears that the maximum number of rainy days takes place between the first quarter and the full moon, and the minimum between the last quarter and the new moon. The number of rainy days in the last of these intervals is to that in the first as 696 to 815, or in round numbers as 5 to 6. And this proportion is not only true of the twenty years taken together, but also of the separate groups of four years, which give analogous numbers. We are therefore to conclude, if we put faith in the observations, that it rains more frequently during the increase than during the wane of the moon.

The above results are confirmed by a series of observations made at Vienna, and discussed by Pilgram in the year 1788. On 100 repetitions of the same phase, Pilgram found the falls of rain to be as follows: new moon, 26, mean of the two quarters 25, full moon 29; consequently at Vienna, as well as at Augsburg and Stuttgart, it rains more frequently on the day of the full than on that of the new moon.

Another element remains to be taken into consideration, namely, the moon's distance from the earth, which admitting the lunar action on the atmosphere, it is natural to suppose will have a marked influence on the phenomena. In fact, Schubler found that during the year, three hundred and seventy-one anomalous

revolutions of the moon which take place in twenty-eight years, the number of rainy days included within the seven days nearest the perigee were 1169, and within the seven days nearest the apogee 1096. From the observations at Vienna, Pilgram found that during 100 lunations, the number of rainy days at the perigee were 36; and at the apogee 20 only.—Thus, other circumstances being alike, the nearer the moon is to the earth, the greater are the chances of rain.

"Confining ourselves," says Arago, "to the principal results, it seems difficult to resist the conclusion, that the moon exercises an influence on our atmosphere; that in virtue of this influence rain falls more frequently towards the second octant than at any other epoch of the lunar month; and lastly, that the chances of rain are fewest between the last quarter and the fourth octant."

The influence of the moon on the terrestrial atmosphere seems also to be rendered evident by observations of a different kind, namely, the mean heights of the barometer at the different lunar phases. On calculating a series of observations made at Padua by the Marquis Poleni, and extending over a period of forty-five years, Toaldo found that the mean height of the barometer at the quarters is greater than its mean height at the syzygies, and that the difference amounts to 0.16 millimetres.

From the observations of M. Flaugergues, made at Viviers, in the department of Ardèche, and comprising a period of twenty years, there results: mean height at the quarters 755.81 millimetres, mean height of the syzygies 755.39, difference 0.42.

From a series of observations made at the Royal Observatory at Paris, and discussed by Bouvard, the following results were found—mean height at the quarters 756.59 millimetres, mean height at the syzygies 755.90, difference 0.69.

Thus we have three distinct series of observations, made at places considerably distant from each other, and all pointing to the same conclusions. The chances are small that such an agreement is merely accidental; and it seems a fair inference that "the moon in our climate does exercise an action on the atmosphere, very small indeed, but clearly indicated by the comparison of a large number of barometric observations." Few, we should think, will be disposed to attach much value to the minute differences above noted.

Admitting, however, the lunar action on the atmosphere to be established, the next question is to determine its nature. Now the moon can be supposed to act on the atmosphere only in one of three ways, either by its attraction, by the light which it reflects, or by obscure emanations of an electric, magnetic, or unknown nature. As the lunar action, of whatever nature it is, causes an inequality of pressure, indicated by the barometrical observations, it would appear, *a priori*, most probable that is exercised in the way of attraction. On this subject M. Arago enters into a pretty long argument, through which our limits will not permit us to follow him. The result, however, is, that if the effects of the lunar attraction on the atmosphere are at all sensible, they must follow a law entirely different from that which is indicated by the above observations. In fact, it is easy to see that if the variation of atmospheric pressure arises from the attraction of the moon, it ought to be precisely the same at the new and full moon, and also at the first and last quarters.—But according to the observations of Flaugergues, the difference of pressure attains nearly its maximum to the quarters, when, according to the theory, it ought entirely to disappear. We may remark, that this subject was examined many years ago, by M. Bouvard, who satisfactorily demonstrated that the atmospheric *tide*, so far as it depends on the same cause which produces the tides of the ocean, and is governed by the same laws, is altogether inappreciable. The conclusion therefore is, that "the in-

equalities of pressure indicated by observation must be referred to some cause different from attraction; to some cause certainly depending on the moon, but of which the nature and mode of action still remain to be discovered.

M. Arago next proceeds to the examination of the popular opinion regarding the influence of the phases of the moon on the changes of the weather. From the observations computed by Toaldo, the ratio of the number of changes of the weather to the number of no changes of the different phases of the moon, was found to be as follows: new moon, 6 to 1; full moon, 5 to 1; first quarter, 2 to 1; second quarter, 2 to 1; perigee, 5 to 1; apogee, 4 to 1; that is to say, of seven new moons, six were accompanied with a change of weather, and at one of them there was no change; of six full moons, five were attended with a change; and at the quarters, the changes were twice as frequent as the continuance of the previous weather.

These results would be decisive of the question, if their accuracy were beyond suspicion, but independently of the arbitrary sense that may be attached to the term change of weather, it appears that Toaldo "does not content himself with attributing to the phases of the moon the changes which take place on the very day of the phase; he classes also, in the same category, the changes of the day that precedes and follows. In certain instances, he extends the lunar action to the second day before and after the phase. In adopting such bases it is to be wondered at, that the moon has appeared to be endowed with so powerful an influence?"

The result of Pilgram's observations at Vienna, is entirely different. During a hundred lunations the number of changes of weather on the days of the respective phases, were as follows:

N. moon, 58	Perigee, 72	N. moon in apogee, 64
F. moon, 63	Apogee, 64	F. moon in perigee, 81
Quarters, 63	N. moon in perigee, 80	F. moon in apogee, 68

It results from the simple inspection of this table that with regard to the changes of weather, the *new moon* is the least active of all the phases. The contrary is proclaimed by popular opinion. The observations, nevertheless, from which the table is deduced, extend over fifty-two years; and as Pilgram was himself a believer in the lunar influence, it may be inferred, that if he committed errors, they would not have a tendency to militate against his own preconceived notions.

Among the ancients the opinion was universally entertained that the different aspects of the moon furnish sure *prognostics* of the future state of the weather.

"It," says Aratus, "on the third day of the moon the horns of the crescent are sharp and well defined, the sky will continue serene during the whole of the month."

This is a notion which we believe to be very prevalent at the present day among the peasantry of our own country. The following is the commentary of Arago:

"In reality, when the moon in the evening begins to disengage herself from the sun's rays, she has always the form of a crescent, terminated by two very sharp horns; but if the atmosphere happens to be troubled the horns appear enlarged. This enlargement, however, is a mere optical illusion, and is occasioned by strongly illuminated clouds, in apparent contact with the moon, and seeming to form a constant part of her body. The fine extremities of the crescent are then lost as it were in the parasitical light which surrounds the moon, and become invisible to the naked eye. All this is rendered evident by employing a telescope, which destroys the illusion."

Many other aphorisms of the same nature might be quoted from Aratus, Theon, Theophrastus, Pliny, and other ancient writers on rural affairs. But they may be dismissed with the general remark that they had their origin in that ignorance which confounds *signs* with *causes*, and are now disregarded, excepting by

the most illiterate and credulous. They are besides at total variance with the theory of the influence of the phases.

The agency of the moon has not been confined, in popular opinion, to the changes of weather; she has been allowed in all ages and countries to exercise a direct and important influence on organic life. Many of the opinions vulgarly entertained on this head are curious, and are founded on well established facts; the error lying, not in the observations, but in the theory which makes the moon the cause of phenomena of which she is only the silent and unconcerned spectator. We may mention one or two of the most remarkable.

"It is generally believed, especially in the neighborhood of Paris, that the moon, in certain months, has a great influence on the phenomena of vegetation. The gardeners give the name of *red moon* (*lune rousse*) to the moon which, beginning in April, becomes full either about the end of that month, or more usually in the course of May. In the months of April and May the moon, according to them, exercises a pernicious influence on the young shoots of plants. They maintain that they have observed during the night, when the sky is clear, the leaves and buds exposed to this light to become red, that is to say, to be frozen, although the thermometer, in the free atmosphere, stood several degrees above the freezing point. They also assert, that if the rays of the moon are intercepted by clouds, and thereby prevented from reaching the plants, the same effects do not take place, under circumstances perfectly similar in other respects with regard to temperature. These phenomena seem to indicate that the light of our satellite is endowed with a certain frigorific influence; yet, on directing the most powerful burning glass or the largest reflectors towards the moon, and placing the most delicate thermometers in their foci, no effect has ever been observed which could justify so singular a conclusion. Hence with philosophers the effects of the April moon are now referred to the class of vulgar prejudices, while the gardeners remain convinced of the accuracy of their observations. A beautiful discovery made some years ago, by Dr. Wells, will enable us, I think, to reconcile two opinions in appearance so contradictory.

"No one had supposed, before Dr. Wells, that terrestrial substances, excepting in the case of a very rapid evaporation, may acquire during the night, a different temperature from that of the surrounding air. This important fact is now well ascertained. On placing little masses of cotton, down, &c. in the open air, it is frequently observed they acquire a temperature of six, seven, or even eight centigrade degrees below that of the surrounding atmosphere. The same is the case with vegetables. We cannot therefore judge of the degree of cold with which a plant is affected during the night by the indications of a thermometer suspended in the free atmosphere: *the plant may be strongly frozen, although the air remains constantly several degrees above the freezing point.* These differences of temperature between solid bodies and the atmosphere only rise to six, seven or eight degrees of the centesimal thermometer, when the sky is perfectly clear. If the sky is clouded, they become insensible.

"It is now necessary to point out the connection between these phenomena and the opinions of the country people regarding the April moon.

"In the nights of April and May the temperature of the atmosphere is frequently only 4, 5, or 6 centigrade degrees above zero. When this happens, plants exposed to the moon,—*that is to say, to a clear sky,*—may be frozen, notwithstanding the indications of the thermometer. If the moon, on the contrary, does not shine—in short, if the sky is cloudy, the temperature of the plants does not fall below that of the atmosphere, and they will consequently not be frozen unless the thermometer indicates zero. It is therefore quite true, as the gardeners pretend, that under thermometrical circumstances precisely alike, a plant may be

frozen or not, according as the moon may be visible or concealed behind clouds. If they are deceived, it is only in their conclusion, in attributing the effect to the light of the moon. The moon's light is, in this case, only the index of a clear atmosphere; it is only in consequence of the clearness of the sky, that the nocturnal congelation of plants takes place; the moon contributes to the effect in no way whatever; although she were hid under the horizon the effect would not be different."

The explanation here given is perfectly satisfactory, and may be extended to some other notions that have prevailed respecting the lunar influence. For example, it is said by Pliny and Plutarch, and is at the present day generally believed in the West Indies that the moon sheds a copious humidity on bodies exposed to her rays, and that her light hastens the putrefaction of animal substances. This opinion is, to a certain extent, countenanced by facts.

"A body exposed to the light of the moon,—*that is to say, to a clear sky,*—becomes, in consequence of its radiation, colder than the surrounding air. Under these circumstances the air deposits a portion of its humidity on the cold surface of the body, which is neither more nor less than the phenomenon of dew, as analysed by Doctor Wells.—Now, animal substances become much sooner putrid when moist than when dry. The observation of Pliny and Plutarch is therefore correct in all its details. It was only necessary to reform the theory, and acquit the moon of the mischief ascribed to her."

Again, it is a commonly received opinion that the light of the moon darkens the complexion. If such an effect is produced by exposure to the moon's rays, its explanation must be sought far elsewhere than in the action of the lunar light, as is demonstrated by the following fact.

"Of all known substances, the chloride of silver is that of which the color suffers the greatest and most rapid change on exposure to light. But a plate of this chemical compound; exposed for a long time to the light of the moon condensed in the focus of a powerful burning glass, is observed to lose nothing of its primitive whiteness."

Nevertheless, the popular opinion is perhaps not altogether destitute of foundation. The skin exposed to the light of the moon,—that is, to a clear sky,—probably acquires, like dead substances, placed in the same circumstances, a temperature several degrees below that of the surrounding air. It is true that the animal heat is incessantly repairing the deficit occasioned by radiation; yet "who would affirm that the physical conditions under which an intense local cold places the epidermis may not alter its texture and modify its shade?"

We shall conclude our extracts, with the following striking passage, from which it might almost be inferred that M. Arago himself is inclined to allow the moon to retain a portion at least of that influence she has been so long supposed to possess in the affairs of the terrestrial world.

"Hippocrates had so lively a faith in the influence of the stars on animated beings, and on their maladies, that he very expressly recommends not to trust physicians who are ignorant of astronomy. The moon, however, according to him, only acted a secondary part; the preponderating stars were the Pleiades, Arcturus, and Procyon.

"Galen showed himself, in this respect, a zealous disciple of Hippocrates, but it was the moon to which he assigned the chief influence. Thus the famous critical days in diseases—that is to say, the 7th, the 11th, and the 21st, were connected with the duration of the principal phases of our satellite, and the lunar influx became the principal pivot of the system of crises."

"With regard to the theory of lunar influence on disease, it still counts a goodly number of partisans. In truth, I know not if the circumstance ought to astonish us. Is it not something to have on one's side

the authority of the two greatest physicians of antiquity; and among the moderns, that of Mead, Hoffman, and Sauvage? Authorities, I admit, are of little weight in matters of science, in the face of positive facts; but it is necessary that these facts exist, that they have been subjected to severe examination, that they have been skillfully grouped, with a view to extract from them the truths they conceal. Now, has this procedure been adopted with regard to the lunar influences? Where do we find them refuted by such arguments as science would acknowledge? He who ventures to treat, *a priori*, a fact as absurd, wants prudence. He has not reflected on the numerous errors he would have committed with regard to modern discoveries. I ask, for example, if there can be any thing in the world more bizarre, more incredible, more inadmissible, than the discovery of Jenner? Well, the bizarre, the incredible, the inadmissible, is found to be true; and the preservative against the small pox is by unanimous consent, to be sought for in the little pustule that appears in the udder of the cow. I address these short reflections to those who may think that in this article I have taken an unnecessary trouble."

(From the National Intelligencer.)

PUBLIC SPIRIT.—STEAM MILL.

Leonardtown, Md. July 17, 1853.

Yesterday, a large number of planters and farmers and other citizens in the vicinity of this place, attended to witness the starting of Mr. H. G. S. KEY's steam mill, just completed. A general invitation had been given, and it was gratifying to see the warm interest taken in behalf of this new experiment—it being the only steam mill erected in any of the lower counties of the Western Shore of Maryland, or on the waters of the Potomac river, below the District of Columbia. At three o'clock, P. M. the hour appointed for starting the engine, Governor THOMAS, who had politely attended on the occasion, threw in the first handful of grain, expressing his anxious wishes for the success of the enterprise, and his confident belief of the public advantage to result from it; and at the same moment, the signal being given, the machinery commenced its works in beautiful style, evincing perfect harmony in all their parts, to the admiration of the numerous spectators. The whole arrangement of the establishment does credit to the enterprising projector, and the execution to his efficient and industrious workmen.

This manufactory is destined to be of incalculable benefit to the surrounding country, either on the Maryland or Virginia shore of the Potomac. Its location is at Leonardtown, a thriving, prosperous village, immediately on Britain's bay, a few miles from Blackstones island, with navigable water for steamboats and bay craft up to a wharf about to be built at the door.

Thus an opportunity will be offered to the planters and farmers of supplying themselves with fresh flour, meal and plaster, of unadulterated quality, as none other will be ground, upon the most favorable terms.

The consequent improvement of lands adapted to its application, by the free use of plaster, should stimulate the agriculturists of St. Mary's and Charles, at least, to avail themselves of the proffered advantages; for in all those lands where good and genuine plaster has been judiciously used, it has proved efficacious. The writer of this is a witness to its beneficial effects upon high, upon low land, as well as upon river bottoms, whether of salt or fresh water. That the furthest of those counties are peculiarly adapted to its beneficial effects has been attested by frequent experiments. Let none then doubt until after fair and patient trial. It is understood that wheat, rye, and corn will be received; and flour, meal and plaster, delivered with the least possible delay.

When the mill had been in operation a sufficient time for all present to examine the machinery, the work done, &c. the company (amongst whom were a

number of ladies, whose *laudible curiosity* had induced them to grace the mill with their presence, which prompted unnumberable applications, from the *bachelors* in waiting, for the station of *mill*, believing that if such were to be the *custom* there would be no danger of starving) were invited to partake of refreshments which had been liberally provided by the hospitable landlord; after which a few remarks were made by Col JENNER, commemorative of the occasion, and deservedly complimentary to the enterprising proprietor. The company dispersed with gratified feelings. How much more so than if they had been called together to witness the pickerings of political contest, is for those to appreciate who enjoyed them. The thanks of all who were present are due to Mr. KEY, as well as the community who will be benefited by his enterprise. That he may be abundantly remunerated for his large investment, indefatigable industry, and public spirit, is anxiously desired by

ARATOR.

Prices Current in New York, July 27.

Beeswax, yellow, 18 a 20. *Cotton*, New Orleans, .15 a 17½; Upland, .14 a 17; Alabama, .14 a 17. *Cotton Bagging*, Hemp, yd. .13 a .21½; Flax, .11 a .15. *Flax*, American 8½ a 9. *Flaxseed*, 7 bush. clean, 15.00 a 15.25; rough, 13.00 a —. *Flour*, N. York, bbl. 5.50 a 5.62; Canal, 5.56 a 5.75; Balt. How'd st. 6.12 a 6.25; Rhd city mills, — a —; country, 6.00 a 6.12; Alexand'a, 6.00 a —; Fredericksburg, 5.87 a —; Petersburg, 5.87 a —; Rye flour, 3.75 a —; Indian meal, per bbl. 3.75 a —, per hhd. 17.00 a —. *Grain*, Wheat, North, 1.18 a —; Vir. — a —; Rye, North, .80 a —; Corn, Yel. North, .74 a .75. *Barley*, — a —; Oats, South and North, .38 a .40; Peas, white, dry, 7 bu. — a —; Beans, 7 bu. 8.00 a 8.50; *Provisions*, Beef, mess, 10.25 a 10.75; prime, 6.00 a 6.25; cargo, — a —; Pork, mess, bbl. 14.50 a 15.50, prime, 11.50 a 11.75; Lard, .9 a .10½.

DURHAM SHORTHORN CATTLE.

I have for sale the following fine animals:

One full blood Bull, twenty months old, sired by Bolivar, out of a first rate imported cow. Price \$200.
One full blood bull, two years old—a very fine animal. Price \$250.
One full bred Heifer, two years old, now springing, but the calf will be but half blooded, being (accidentally) by a common bull. She is a very fine Heifer, and will be sold for \$225.

Less than Full Blood.

One Bull, three years old, fifteen-sixteenths Durham; has been pronounced by good judges as fine an animal as was ever in the United States. He would be worth twice the price now asked for him if he had the other sixteenth of Durham blood. He will be sold for \$300.
One Bull, fifteen months old, from good stock, seven-eighths Durham. Price \$225.
One Bull, three years old, half blood Durham, a very handsome animal, and from good stock. Price \$150.
One Cow, eight years old, seven-eighths Durham, a fine breeder, and now in calf by a full blood bull. Price \$100.
Three Milch Cows, half blood Durham, very good milkers, and of good size and form. They will be sold for \$50 each.

I. I. HITCHCOCK.

Amer. Far. Establishment.

A BULL,

One year old, sired by Bolivar, out of a very deep milker of fifteen-sixteenths Durham blood, (consequently he lacks but one-thirty-second part of being full blooded,) will be sold for \$150. Inquire of

I. I. HITCHCOCK,

American Farmer Establishment.

EARLY YORK CABBAGE,

And all other GARDEN SEEDS, suitable for fall sowing, are for sale at the American Farmer Seed Store, by

I. I. HITCHCOCK.

WANTED, A BAKEWELL RAM,

One year old or more, for which a fair price will be paid. Inquire of

I. I. HITCHCOCK,
American Farmer Establishment.

BUCK WHEAT.

A few bushels of very superior quality for seed, for sale at the American Farmer Establishment, at \$1.25 per bushel.
I. I. HITCHCOCK.
N. B. Half a bushel is required to seed an acre.

A DEVON BULL.

Six years old, a first rate animal in every respect, for sale low. He is believed to be decidedly the best animal of the kind in Maryland. Price \$200.
Address
I. I. HITCHCOCK,
American Farmer Establishment.

BAKEWELL SHEEP.

The Subscriber has become agent for John Barney, Esq. for the sale of his celebrated Bakewell Sheep. The stock now on hand for sale, is the following:
Eight or ten EWES, of good age and quality, at prices from \$40 to \$50.
About the first of September next, I shall have from the same flock six or eight Rams of this year's stock. Price \$50 each.

I shall have about the same time, from the flock of another celebrated breeder, a few Ram lambs—half Bakewell and half Southdown. Prices from \$30 to \$40 each. Address
I. I. HITCHCOCK,
American Farmer Establishment.

TALL MEADOW OAT GRASS SEED.

Just received at the American Farmer Establishment, 100 bushels Tall Meadow Oat Grass Seed, of first quality, just harvested and for sale, at \$2.50 per bushel, by
I. I. HITCHCOCK

TO FARMERS.

J. S. EASTMAN would inform the public, that he has in store a good supply of Grain and Grass Seythes, Grain Cradles, Seythe Snaths by the dozen or single, Shovels, Spades, Manure and Hay Forks.

Field and Garden Hoes, and a general assortment of Garden Tools manufactured expressly for him.

Patent Cylindrical Straw Cutters of various sizes and prices, also common Cutting Boxes, Wheat Fans, Corn Shellers, Harrows and Cultivators, and a general assortment of Ploughs, and all kinds of Castings for Davis' Improved Patent Ploughs, with a great variety of other Agricultural Implements.

And also Fox and Borland's Patent Spring Concave Threshing Machines ready made on hand.

Likewise a general assortment of Garden Seeds, such as he believes to be genuine.

He is also Agent for an Iron Foundry, in the vicinity of Baltimore, and can furnish at short notice, any kind of Iron Castings of superior quality, on as reasonable terms as can be had in this city. The quality of Casting can be seen at any time, at his store in Pratt street, near Hanover street. Ap. 26.

TURNIP SEED, BUCKWHEAT, &c.

400 lbs. White Flat and Red Top Turnip Seed.

100 lbs. Ruta Baga or Swedish do do

The above is of the present years' growth and raised under the immediate superintendence of Robert Sinclair, whose long success in raising this article warrants us in recommending it with the greatest confidence.

Also, Early White Dutch Tankard.

Yellow Bullock and Yellow Stone Turnip.

200 lbs. Fall Radish Seed, consisting of White and Black Spanish, Long White Summer, &c.

100 lbs. prime London Early York Cabbage Seed, Early George, Green Savoy, Flat Dutch, and many other kinds suitable for Fall Sowing.

IN STORE:

50 bushels Seed Buckwheat.

100 bushels Herds grass.

50 bushels Tall Meadow Oat Grass.

200 lbs. Canary Seed.

1500 lbs. Yellow Locust Seed.

150 lbs. Yellow Mustard Seed.

WANTED.—Clover, Timothy and Orchard Grass Seed, for which the highest price will be given.

July 13.

SINCLAIR & MOORE.

WANTED,

All kinds of GRASS SEED, for which a fair price will be given, by
I. I. HITCHCOCK,
American Farmer Establishment.

BALTIMORE PRICES CURRENT.

BALTIMORE MARKET.—Fresh ground flour continues to maintain its former price; the business in Howard street, however, is principally confined to retailing. The wagon price is \$6.00, with occasional variations in favor of favorite brands. Wheat has declined a little, in consequence of the increased supply of new wheat.

Tobacco.—Seconds, as in quality, 3.00 a 5.00; do. ground leaf, 5.00 a 9.00.—Crop, common, 3.00 a 5.00; brown and red 4.50 a 6.00; fine red, 6.00 a 8.00; wrappery, suitable for segars, 6.00 a 15.00; yellow and red, 9.00 a 15.00; yellow, 16.00 a 20.00.—Fine yellow, 18.00 a 25.00.—Virginia, 4.00 a —.—Rappahannock, 3.00 a 4.00.—Kentucky, 3.50 a 8.00. The inspections of the week comprise 440 hlds. Md.; 108 hlds. Ohio; and 3 hlds. Penn.—total 551 hlds.

FLOUR—best white wheat family \$6.75 a 7.25; super; Howard-street, 6.12½ a 6.25; city mills, 6.25 a 6.50—city mills extra 6.50 a —;—CORN MEAL bbl 3 62½;—GRAIN, new red wheat, 1.15 a 1.20; white do 1.25 a 1.30 —CORN, white, 62 a 63, yellow, 64 a 65;—LVE, 65 a 67 —OATS, 28 a 31.—BEANS, 75 a 80—PEAS, 65 a 70—CLOVER-SEED 8.00 a —TIMOTHY, 3.00 a —ORCHARD GRASS 3.00 a —Tall Meadow Oat Grass 2.25 a 2.50—Herd's, 1.00 a —Lucerne —a 37½ lb.—BARLEY,—FANSEED 1.37 a 1.50—COTTON Va. 12 a 13½—Low. 14 a 16½—Alab. 12 a 15—Tenn. 12 a 13; N. Car. —a —; Upland —a 16½—WHISKEY, hlds. 1st p. 26 a;—in bbls. 30 a 31½—WOOL, Washed, Prime or Saxony Fleece 45 a 50; American Full Blood, 38 a 42; three quarters do. 33 a 38; half do. 30 a 33; quarter do. 28 a 30; common 25 a 28. Unwashed, Prime or Saxony Fleece, 25 a 30; American Full Blood, 22 a 25; three quarters do. 20 a 22; half do. 18 a 20; quarter do 16 a 18; common, 16 a 18 HEMP, Russia, ton, \$180 a 190; Country, dew-rotted, 6 a 7c. lb. water-rotted, 7 a 8c.—Feathers, 37 a 38;—Plaster Paris, per ton, 4.25 a;—ground, 1.50 a — bbl. Iron, gray pig for foundries per ton 38.00 a —; high pig for forges, per ton, 28.00 a 30.00; bar Sus. per ton, 75.00 a 85.00.—Prime Beef on the hoof, 5 75 a 6.50—Oak wood, 3.00 a 3.25; Hickory, 4.00 a 4.50; Pine, 2.00.

CONTENTS OF THIS NUMBER.

Editorial; The Moon; Agricultural School—Tallavera Wheat—Large Mustard—Tobacco—Last Winter in Europe—Culture of Tea—Grey Oxen of Italy—Foreign Markets—On the Management of a Dunghill, by Robert Somerville, Esq. of Haddington, Scotland: Defects of the present mode of Management; Bad effects of a Dunghill placed in a Hollow or on a Declivity or Sandy Bottom; Proper Situation for a Dunghill—On the Culture of Lucerne as practised in England—Preparation of Seed Corn and Wheat—Bone Manure for Corn—Germination of Seeds—Successful Method of Cultivating the Chrysanthemum Indicum—Sunflowers—Essay on Cooking Food for Horses, by Mr. Dix, Veterinary Surgeon—To make an Incombustible Wash and also the Stucco Whitewash—Review of M. GENERAL

Agricultural and Horticultural Establishment:

COMPRISING,

A Seed and Implement Store, a General Agricultural Agency, and the Office of the AMERICAN FARMER, at No. 16 South Calvert street, Baltimore: in connexion with a Stock and Experimental Farm, Garden and Nursery in the vicinity.

☞ An extra number of the Farmer, containing a prospectus of the "Establishment," and a "Catalogue of Seeds," &c. kept for sale, shall be sent GRATIS to any person who shall by mail or otherwise furnish his address for that purpose.

AGENTS FOR THE FARMER.—All postmasters are requested to act as agents for the Farmer, and to require a strict compliance by subscribers with the terms, especially the third item. They are authorised to retain one dollar for each new subscriber, and ten per cent. on all other collections. The list of special agents is published in the Farmer every third week. (Terms next week.)

☞ DIRECTION OF LETTERS.—Address all BUSINESS letters concerning the Farmer, the store, or the agency, to the proprietor, "I. Irvine Hitchcock, Baltimore, Md."

Printed by J. D. Toy, corner of St. Paul and Market streets.

THE FARMER.

BALTIMORE, FRIDAY, AUGUST 9, 1833.

PRICES OF WHEAT, &c. We often hear complaints from farmers of unfair dealing by millers and purchasers of wheat and other grain. The *Easton Gazette* recently contained a long article on the subject. It may well be supposed that we should look at this question with an eye peculiarly single to the interest of the farmers. Indeed we have been deeply impressed with the idea that merchants and millers did take advantage of a full supply of wheat to reduce the price to a degree not warranted by the price of flour. But we have changed our mind. After a long and intimate acquaintance with the dealers in grain and flour, and after much observation, we have satisfied ourselves that no undue advantage is or can be taken of the farmers. Like all other branches of the mercantile profession, dealers in wheat do purchase as cheap as they can, and sell as high as they can.—But in an open market, subject to all the operations of spirited competition and enterprize, among some hundred dealers, the idea of a combination to purchase wheat at a rate uncalled for by the price of flour, is out of the question.—We have seen millers give a price for wheat in a time of scarcity that they knew could not be made out of the flour; but being under the necessity of having the flour, they were obliged to purchase the wheat at any price. We have also seen them refuse to buy wheat at a dollar and twenty cents a bushel, when they were asking \$6 per barrel for flour. Now here are two extreme cases. In times of a scarcity of wheat, millers must have enough to supply their orders, let it cost what it will; and they are then obliged to pay too much for it. But when "the harvest is ended," and every body is sending his wheat to market, the supply very soon gets above the demand. It is at this time that the transactions occur of which the farmers complain; and we think we can explain away all cause of such complaints.

It is true that at this time the price of wheat, and that of flour bear no proportion to each other. Flour will be selling at \$6, we will say, and the price of wheat will be only \$1 a 1.10. Now for the cause. At this same season the exportation of flour is very trifling, and there is nothing but a retail demand. It will not do to grind up large quantities of flour in the hot season to await any future demand for exportation; neither will it do to lay up large stores of wheat at prices equal to the present proportionate price of flour; for, just as soon as millers may safely grind large quantities of flour, the price of it declines. The only chance there is for a safe investment in wheat, at a price proportionate to the present price of flour at this season, is the possibility of a favorable change in some foreign market—a chance that every body must admit to be entirely too uncertain to authorise such investment of money. If millers had a reasonable certainty that they would obtain the price for the flour they make from the wheat, that such flour is now selling for, most certainly they would give the proportionate price for the wheat. And this is a contingency not within the control of the millers or any other set of men. The present state of trade has reduced all branches of commerce to the minimum rate of profit; and therefore, if wheat was reduced in price, materially below what was required by the price and demand for flour, present and prospective, persons enough, other than ordinary dealers, would be found to step into the trade, and speculation would speedily advance the price to its maximum rate. Does any one suppose that a cargo of wheat could be brought into open market in Baltimore, and be purchased by any dealer or set of dealers, at any material reduction from the price required by the state of the flour market? If such a supposition exists in any mind it may as well be dismissed, for the reader may be assured, that the spirit of competition allows of no such transaction.

There is one remedy that farmers can always command for any such grievance, real or supposed; and, that is, they can *time* their marketing better. If they would hold on to their wheat until the cool weather, they would then be able to come to market during the press of the demand for flour for exportation. We do not say, that they would then get better prices than they now get, but that they would then get a price fully proportionate to that of flour.

We are not sure that we have succeeded in the attempt to explain away the cause of complaint. It is a matter extremely hard to comprehend in all its bearings. But, of one thing our readers may be assured, and that is, that if we were satisfied that any undue advantage was taken of them in this matter, we should be the first to expose the transaction. Let them rest satisfied, that the spirit of trade will always compel dealers to pay fair prices for all articles of necessity.

NEW PLOUGH.—The *Courier des Etats Unis* contains an article from a French paper, giving an account of the invention of a new plough by a farmer of the name of Grange, at Harol in the department of Vosges. No particular description is given of the instrument itself; but the prefect of the department, in a communication addressed to an agricultural academy, speaks of it in terms of great admiration, and applauds the disinterestedness of the inventor, who declined taking a patent.—Mr. Grange says, that having been compelled from infancy to labor for many years with a plough drawn by six horses, on a soil abounding with stones, he was induced to attempt to introduce some improvement, which would enable him, with less effort, to preserve a proper direction in the furrow, which he had found impossible as it was then constructed. After having succeeded to his own satisfaction, a trial of his invention was made in the presence of the committees of four agricultural societies, and of a great throng of people. The plough, without being held or touched by any one, except at the commencement of a new furrow, preserved its direction perfectly, turning out regular and uniform furrows. It was drawn by four horses. With the plough of the country, says the prefect, twelve horses could not have done the work with the same expedition and success.

CULTURE OF SILK.—Public attention in this country appears latterly to be turning, to an extent hitherto unequalled, towards the interesting, and important subject of raising silk. We are gratified to perceive this, because, from the few experiments that have already been made, we believe it has been fully proved that silk may be made here, equal, if not superior in quality, to that produced in any other part of the world, and with equal facility. A gentleman of this village, in a highly commendable spirit of enterprize, has recently procured and planted out a quantity of Mulberry trees, and brought from Connecticut a parcel of silkworms, for the purpose of showing to our farmers how easily and cheaply they may produce their own silk, as well as make the article a profitable commodity for market; and also with a view of ultimately extending the business himself. These worms, we understand, he has divided with a farmer of Macedon, who has a young mulberry orchard, and intends to make the article of silk one of the staple products of his farm.

Among the anecdotes we have heard related by the gentleman above alluded to, (who is himself a yankee, as might be easily guessed,) since his recent return from the "land of inventions," by way of illustrating the great profits that may be derived from this business of raising silk. We will mention the following, which is peculiarly characteristic of what is not inaptly termed "yankee enterprise."—And what renders the story more interesting, is the fact that the speculator was a young lady. In one of the towns of Connecticut, somewhat remote from the silk districts, a farmer in moderate circumstances owns a small mulberry orchard, which was left to him by his father,

who died a few years since, before the same had become old enough for use. It had been entirely neglected, until during the last season, when it was discovered by, and attracted the attention of a young lady from Mansfield, a town already considerably distinguished for its rich productions of silk, who applied to the owner for the use of it for that season. A bargain was finally concluded, upon the terms proposed by the fair applicant—the business to be conducted on shares—she to bring her worms from Mansfield, and do all the work, and the owner of the mulberry trees to have one-half of the product. At the proper period the necessary fixtures were arranged, the worms hatched, and operations commenced. During the first three weeks the worms requiring only a small share of her time, she contrived to "change work" with several of the families in the neighborhood, arranging her bargains so as to have the work returned when she might require assistance—providing also for her board during the time it would be necessary for her to remain in the place. In this way she managed to accomplish the whole enterprize without any expense out, and at the expiration of six or seven weeks she had produced 54 lbs. of raw silk, worth in cash \$1 per lb. which being divided according to contract, left her share 27 lbs. She thus acquired for her month and a half's services a net proceed of \$105.—*Palmira Sentinel*.

[The above anecdote is incorrect. The young lady may have produced cocoons enough to make 54 lbs. raw silk in the time stated; but she could not have reeled them, and thus "produced 54 lbs. of raw silk." It is a good day's work to reel one pound of raw silk a day, and thus it would have required more than the "six or seven weeks" to reel the 54 lbs. to say nothing of the six weeks which it required to produce the cocoons. Notwithstanding the error above noticed, however, it will be perceived that the young lady made a very handsome job of it. Allowing her forty-two days for producing the cocoons, (six weeks,) and two months for reeling them into raw silk, she made more than a dollar a day by it, with all the disadvantages attending an itinerant establishment. Had she possessed mulberry trees at home, and been prepared with proper fixtures and help, she would have doubled the above result.—*Ed. Amer. Farmer*.]

SILK MANUFACTURE.—One of the most gratifying exhibitions we ever witnessed is that of the silkworm in all its stages, with the mulberry leaves, eggs, cocoons, chrysalis, miller, &c. together with a complete domestic process of manufacture, which may be seen at the Agricultural Warehouse, North Market st. Boston. The machine which is there in motion was invented last winter by Mr. Adam Brooks, of Scituate, Mass. and a patent of it, which we have seen, was issued on the late 29th June. It is an improvement, as it seems to us, of vast importance; for unlike the Piedmontese wheel, heretofore chiefly used, which only performed the reeling process, it combines the reeling and twisting; and the saving in labor is such in consequence, that one hundred and fifty skeins can be made in a day by one woman and a little girl to turn this improved wheel, as easily as forty can by the old.—This we learn from those who have tried both. One of the new machines is used in Connecticut, and another in New York, besides those in the family of the ingenious inventor, who now devote their time in a great measure to this business.

Mr. B. is one of the Society of Friends. His wife, who superintends the wheel, and has paid some attention to silk making for several years, had made frequent complaints of the labor lost by the old machine. Her husband doubted the practicability of amending it, and told her so in plain terms; but went to thinking, it seems, and in about three weeks produced this capital improvement. Mrs. B. says it was formerly a very hard day's work to make thirty skeins: she can now make one hundred in ordinary hours.

AGRICULTURE.

(From the (Edinburg) Farmer's Magazine.)

ON THE MANAGEMENT OF HAY.

MEMBERS, EDITORS:

If you think the following observations on the management of *hay* deserving of notice, they may be inserted in your next number.

The treatment of *hay* is a subject of high importance to the agricultural interest of Britain, not only as a valuable article of produce, but as constituting a bulky and essential part of the food of our domestic animals, upon which their health and usefulness in a great measure depend.

Where such a valuable interest is at stake, we might naturally expect to see experiments made, and a suitable degree of attention paid, to form a regular system of management. It is much to be regretted, that in many parts of the island, no such attention has been paid; and the treatment, especially in many parts of North Britain, is slovenly in the extreme, and very ill calculated to secure and preserve, in the highest degree of perfection, that flavor, and those nourishing qualities, without which, neither hay, nor indeed any description of herbage, can be valuable.

The first consideration in the treatment of hay, is the period at which it should be cut, and the weather most proper for that operation. The time most proper for cutting the different kinds of grain, together with every step of the after-management, are points well understood, and for the most part strictly observed, by every farmer being sensible, that any neglect of,

deviation from these rules, will, by impairing the quality both of the grain and straw, be productive of much trouble and loss to himself. It is somewhat surprising, that the same kind of reasoning should not have been applied to the management of hay; as any diminution of its value, arising from improper treatment, must be equally prejudicial both to the grower and consumer of that article, as to the grower and consumer of grain.

The practice of many farmers in North Britain is, to allow their hay, not only to attain its ultimate growth, but even to make some progress towards decay, before it is cut: to obtain a bulky crop, being their chief object, every other consideration is disregarded; and neither the period of growth at which the cutting ought to commence, the weather most proper for that operation, nor indeed any step of the after-management, are regulated by first rules. In place of cutting the crop during dry weather, and when it is free from every other but its own natural moisture, it is very often cut in a wet state, and on that account must remain in the swarth a considerable time before it is fit for being put into cocks, during which it requires to be frequently turned and exposed to the sun and atmosphere, for the purpose of drying it: in that way, a considerable proportion of its natural juices are dissipated; and by the time it is dry enough for putting into the stack, it has lost not only its flavor, but a great part of its most valuable properties; an evil that is farther increased, if much rain happen to fall either immediately after the cutting, or at any period before it is put into cocks. In that case, a still greater loss of its nourishing properties, and a consequent diminution of its value, must happen.

The consequences of this management are felt in a variety of shapes, in every district where it prevails. In the lower districts, the mischief is comparatively small, owing to the mildness of the winters, the great quantity of rich faggage every where to be met with, and the abundance of corn straw, and other wholesome articles of food, with which these parts abound. In the hilly and upland districts, however, the case is very different; and the loss arising from the neglect and mismanagement of their hay is great, almost beyond calculation. In those elevated regions, the winters are, for the most part, of uncommon length

and severity; little straw is produced; sown grasses, turnips, and potatoes, are equally scarce. In that way, the chief dependence of the farmer, for winter food to his stock, falls upon the hay, which, when the quality is bad, and other articles scarce, induces debility and disease to such a degree, that a great part of the stock either die, or are reduced to a state of extreme weakness during the winter; and when the spring arrives, the green food has such an effect upon the bowels of those who have survived, that many of them die also.
